Fitting lines to points in the plane

Annett Püttmann

September 21, 2011

Abstract

We seek for lines of minimal distance to finitely many given points in the plane. The distance between a line and a set of points is defined by the L^p-norm, $1 \leq p \leq \infty$, of the vector of vertical or orthogonal distances from the single points to the line.

The known properties of optimal lines are deduced by elementary considerations and represented using a uniform language for the different choices to define the distance from a line to a set of points.

1 Introduction

This article deals with an elementary problem. We seek for a line that is as close as possible to a finite set of points in the plane. The regression line is a well-known solution and it is even easy to compute. However, it is only one out of many possible answers, since the optimal line depends on the definition of the distance between a line and a set of points.

1.1 Distance between a line and a set of points

There are several useful ways to measure the distance between a line and a finite set of points. Usually, this is done in two steps: First the distance d_j between a single point p_j and a line is defined. Then these distances are combined to a distance between the line and the point set $\{p_1, \ldots, p_m\}$.

We consider the vertical and the orthogonal distance between a point and a line. The vertical distance between a point (x_j, y_j) and the graph of a linear function $y(x) = ax + b$ is defined by $d_j = |y_j - ax_j - b|$. To emphasize that the solution should be a graph of a (linear) function this distance is also called algebraic distance. The orthogonal distance between a line g and a point p_j is the length of the line segment connecting p_j and g perpendicular to g. To compute this distance the euclidian inner product is used. Therefore, this distance is also called euclidian or geometric distance.

The distance between a point set $\{p_1, \ldots, p_m\}$ and a line is defined by the L^p-norm of the vector $(d_1, \ldots, d_m) \in R^m$, $1 \leq p \leq \infty$. For $p = 2$ we want to minimize the sum of squares $d_1^2 + \ldots + d_m^2$ of the distances of the single points. This is the classical method of least squares. The L^2-norm is preferred in statistics. For $p = 1$ and $p = \infty$ we want to minimize the sum $d_1 + \ldots + d_m$ respectively the maximum $\max\{d_1, \ldots, d_m\}$ of the distances of the single points. These quantities occur in optimization problems. Then the L^p-norm is a natural generalization. Furthermore, the investigation of the function $d_1^p + \ldots + d_m^p$ for all $1 \leq p$ connects the extreme norms ($p = 1$, $p = \infty$) to the case $p = 2$.

1.2 Goals

The results of this article are known, partially for a long time, (e.g. [1], [2], [3], [5], [6], [8], [9]) or can be rather easily derived for some distances. But the facts are spread and are often formulated according to the needs of the applications. In this article the results are presented in a uniform language accessible to a broad audience. The results are deduced by elementary considerations that require only basic linear algebra and calculus. Therefore, the appendix contains the necessary facts on convex sets and convex functions.

Due to the homogeneous representation one can easily observe how the properties of the objective function f, the suitable methods and the set of optimal lines change using different definitions of the distance. Here are two examples: The algebraic distance leads to convex or even strictly convex functions. Using the geometric distance we loose the convexity in one variable but we gain the compactness of the domain of definition of f. Differential calculus provides explicit formulas of optimal lines for $p = 2$. For $p = 1$ and $p = \infty$ the function f is not even differentiable at all points but it is piecewise linear. So the global minimum can be determined comparing finitely many values of f.

Despite the differences of the distances investigated here there is one basic idea behind all the solutions. Properties of optimal lines are obtained observing the behavior of f while translating and rotating a line. If f is differentiable, then partial differentiation yields a system of equations for the critical points of f, else this approach gives at least information about the location of optimal lines.

Moreover, dealing with this elementary optimization problem, that can be satisfactory solved by simple arguments in many cases, motivates further questions in different fields of mathematics. For example, what are the effects of small changes of the given point set or the parameter p. If explicit formulas of the optimal lines are not available, then one needs fast algorithms to manage the input data ($p = 1$ and $p = \infty$) or to numerically approximate the solution ($p \neq 1, 2, \infty$). It is even more challenging to fit other objects such as circles or ellipses to point sets [3]. In these cases the basic questions of existence and uniqueness of objects with minimal distance are already more difficult to answer.

1.3 Symmetries

The algebraic and the geometric distance and the associated optimal lines, behave differently regarding coordinate changes.

The geometric distances are by definition invariant under isometries, these are translations, rotations and reflections. The algebraic distances are invariant under translations and reflections in the coordinate axes or a point.

If the distance is invariant under an (affine) transformation $A : \mathbb{R}^2 \to \mathbb{R}^2$, then a line g has minimal distance to the point set $\{p_1, \dots, p_m\}$ if and only if the line $A(g)$ has minimal distance to the point set $\{A(p_1), \dots, A(p_m)\}$, i.e., the set of optimal lines is equivariant with respect to transformations which do not change the distance. In addition, the set of algebraically optimal lines is equivariant with respect to scalings of the coordinates, i.e., $(x, y) \mapsto (\lambda x, \mu y)$ with $0 \neq \lambda, \mu \in \mathbb{R}$, and the set of geometrically optimal lines is equivariant with respect to dilations, i.e. $(x, y) \mapsto (\lambda x, \lambda y)$ with $0 \neq \lambda \in \mathbb{R}$.

It is useful to consider the symmetries of the point set in order to find the appropriate definition of a distance for a specific application, to restrict the domain of definition of f, or to simplify determination of the optimal line for strictly convex functions f, since the optimal line is unique in that case.

1.4 Point sets with multiplicities

In this article we work with the standard assumption that the given points $p_1, \dots, p_m$ are pairwise distinct, i.e., $p_j \neq p_k$ for all $j \neq k$, and $m \geq 2$. Investigating the algebraic distances we additionally assume that the x-coordinates $x_1, \dots x_m$ of the points $p_j = (x_j, y_j)^T$ are pairwise distinct. It is easier to formulate the results in this context.

For each distance considered here we discuss how the main statement changes if the standard assumption is omitted. Therefore, our set up covers also distances which come from weighted norm on $(d_1, \dots, d_m)$, e.g., $\sum_{j=1}^m n_j d_j^p$ with $n_j \in \mathbb{N}$.

2 Method of least squares - L^2-norm

In this section we minimize the L^2-norm of $(d_1, \dots, d_m)$. We consider the function $f(g) = \sum_{j=1}^m d_j^2$. The function f is a quadratic polynomial in the parameters of a line for the algebraic and the geometric distance. Using differential calculus we derive explicit formulas of the optimal lines.

2.1 Linear regression - minimal algebraic L^2-distance

Given points $p_j = (x_j, y_j)^T \in \mathbb{R}^2$, $j = 1, \dots, m$, we determine a linear function $y(x) = ax + b$, $a, b \in \mathbb{R}$, with minimal algebraic L^2-distance to the point set $\{p_1, \dots, p_m\}$, i.e., the minimum of the function $f : \mathbb{R}^2 \to \mathbb{R}$ defined by

$$f(a, b) := \sum_{j=1}^{n} (y_j - y(x_j))^2 = \sum_{j=1}^{m} (y_j - ax_j - b)^2.$$

This approach excludes lines which are parallel to the y-axis ($x = c$). Therefore, we assume $x_j \neq x_k$ for all $j \neq k$. In particular, the points $p_1 \dots, p_m$ are pairwise distinct.

2.1.1 Critical points

The function f is differentiable and

$$\begin{aligned} df = (f_a, f_b) &= \left(-2\sum_{j=1}^{m}(y_j - ax_j - b)x_j, -2\sum_{j=1}^{m}(y_j - ax_j - b)\right) \\ &= 2\left(-\sum_{j=1}^{m} x_jy_j + a\sum_{j=1}^{m} x_j^2 + b\sum_{j=1}^{m} x_j, -\sum_{j=1}^{m} y_j + a\sum_{j=1}^{m} x_j + mb\right). \end{aligned}$$

The critical points of f are given by the solution of the following system of equations:

$$a\sum_{j=1}^{m} x_j^2 + b\sum_{j=1}^{m} x_j = \sum_{j=1}^{m} x_jy_j, \quad a\sum_{j=1}^{m} x_j + bm = \sum_{j=1}^{m} y_j \tag{1}$$

2.1.2 Convexity

The function f is convex, because the summands $(ax_j + b - y_j)^2$ are convex functions. These summands are strictly convex if and only if $x_j \neq 0$. Since the inequality $x_j \neq 0$ holds for at least one index j, the function f is strictly convex. This can be checked directly using the Hesse-matrix H_f:

$$H_f = \begin{pmatrix} \sum_{j=1}^{m} x_j^2 & \sum_{j=1}^{m} x_j \\ \sum_{j=1}^{m} x_j & m \end{pmatrix}, \quad \det(H_f) = m\sum_{j=1}^{m} x_j^2 - \left(\sum_{j=1}^{m} x_j\right)^2$$

It follows from the Schwarz inequality that

$$\left(\sum_{j=1}^{m} x_j\right)^2 = \left(\sum_{j=1}^{m} x_j \cdot 1\right)^2 \leq \left(\sum_{j=1}^{m} x_j^2\right)\left(\sum_{j=1}^{m} 1^2\right) = m\sum_{j=1}^{m} x_j^2,$$

where equality holds if and only if $\vec{x} = (x_1, \ldots, x_m)$ is a multiple of the vector $(1, \ldots, 1)$. Since $x_1, \ldots, x_m$ are pairwise distinct, we have $\sum_{j=1}^{m} x_j^2 > 0$ and $\det(H_f) > 0$. The matrix H_f is strictly positive definite at all points $(a, b) \in \mathbb{R}^2$.

There exists exactly one critical point, since the function f is strictly convex. The function f attains its local and global minimum at this unique critical point.

2.1.3 Globale minimum

The solution of the system of linear equations (1) gives the global minimum of the function $f : \mathbb{R}^2 \to \mathbb{R}$. The second equation means that the optimal line contains the center of mass of the points $p_1, \ldots, p_m$

$$\bar{p} := \frac{1}{m}\sum_{j=1}^{m} p_j = (\bar{x}, \bar{y})^T \text{ with } \bar{x} = \frac{1}{m}\sum_{j=1}^{m} x_j,\ \bar{y} = \frac{1}{m}\sum_{j=1}^{m} y_j. \tag{2}$$

Thus $b = \bar{y} - a\bar{x}$.

Moving the origin to the center of mass we obtain the new coordinates $\tilde{x} := x - \bar{x}$, $\tilde{y} := y - \bar{y}$, $\tilde{x}_j := x_j - \bar{x}$ and $\tilde{y}_j := y_j - \bar{y}$. System (1) transforms into the equations $\tilde{a}\sum_{j=1}^m \tilde{x}_j^2 = \sum_{j=1}^m \tilde{x}_j\tilde{y}_j$ and $\tilde{b} = 0$ for the optimal line $\tilde{y} = \tilde{a}\tilde{x} + \tilde{b}$, since $\sum_{j=1}^m \tilde{x}_j = \sum_{j=1}^m \tilde{y}_j = 0$. Set

$$S_{xx} := \sum_{j=1}^m \tilde{x}_j^2 = \sum_{j=1}^m (x_j - \bar{x})^2,\ S_{xy} := \sum_{j=1}^m \tilde{x}_j\tilde{y}_j = \sum_{j=1}^m (x_j - \bar{x})(y_j - \bar{y}). \tag{3}$$

Theorem 1. *Let $p_j = (x_j, y_j)^T$, $j = 1, \dots, m$, such that $x_j \neq x_k$ for all $j \neq k$. There exists a unique linear function $y(x) = ax + b$ with minimal algebraic L^2-distance to the set $\{p_1, \dots, p_m\}$. This function has slope S_{xy}/S_{xx} and its graph contains the center of mass of the set $\{p_1, \dots, p_m\}$, i.e.,*

$$y(x) = \frac{S_{xy}}{S_{xx}}(x - \bar{x}) + \bar{y}. \tag{4}$$

Proof. The translation $(x, y) \mapsto (\tilde{x}, \tilde{y})$ does not change the slope. □

Corollary 1. *If the set $\{p_1, \dots, p_m\}$ is invariant under the reflection in the line $x = \bar{x}$, then $S_{xy} = 0$.*

Proof. Since the optimal linear function is unique, it is invariant under the reflection in the line $x = \bar{x}$. The graph of the optimal function is not the line $x = \bar{x}$. Thus, it is perpendicular to $x = \bar{x}$. □

Remark 1. Theorem 1 remains true if the condition $x_j \neq x_k$ for all $j \neq k$ is weakened to there existence of indices $j \neq k$ satisfying $x_j \neq x_k$. However, if $x_1 = \ldots = x_m = \bar{x}$, then the graph of any linear function $y(x) = a(x - \bar{x}) + \bar{y}$ with $a \in \mathbb{R}$ is an algebraically L^2-optimal line.

2.1.4 Generalizations

Similarly, there exists a unique linear function $y(x_1, \dots, x_n) = \sum_{i=1}^n a_i x_i + a_0$ having minimal algebraic L^2-distance to a given finite set in $\mathbb{R}^{n+1}$. Whenever a finite set in the plane has to be approximated by functions which are linear in the parameters to be optimized, the method that worked in this section can be applied, because the critical points of the convex objective function are the solution of a linear system of equations.

2.2 Minimal geometric L^2-distance

Given pairwise distinct points $p_j \in \mathbb{R}^2$, $j = 1, \dots, m$, we determine lines $g \subset \mathbb{R}^2$ with minimal geometric L^2-distance to the point set $\{p_1, \dots, p_m\}$, i.e., the minimum of the function $f : \mathbb{R} \times S^1 \to \mathbb{R}$ defined by

$$f(c, n) := \sum_{j=1}^n (c - \langle p_j, n \rangle)^2.$$

Here, a line $g \subset \mathbb{R}^2$ is described by one of its normal vectors $n \in S^1$ and a point $q_0 \in g$. The points of the line g are the solutions of the equation $\langle q, n\rangle = \langle q_0, n\rangle =: c \in \mathbb{R}$, i.e., $g = \{q \in \mathbb{R}^2 : \langle q, n\rangle = c\}$. The geometric distance between p_j and g is given by $|c - \langle p_j, n\rangle|$ (see subsection 2.2.1).

2.2.1 Geometric distance between a point and a line

For $q_j \in g = \{q \in \mathbb{R}^2 : \langle q, n\rangle = c\}$ the equation $d_j = \min_{q\in g} \|q - p_j\| = \|q_j - p_j\|$ holds if and only if $q_j - p_j \perp g$. In the plane, the vector $p_j - q_j$ is perpendicular to the line g if and only if the vector $p_j - q_j$ is a multiple of the normal vector n of the line, i.e., $q_j - p_j = \lambda n$. In that case, $q_j = p_j + \lambda n$ and $d(p_j, g) = |\lambda|$. Now,

$$c = \langle q_j, n\rangle = \langle p_j + \lambda n, n\rangle = \langle p_j, n\rangle + \lambda \|n\|^2 = \langle p_j, n\rangle + \lambda,$$

since $q_j = p_j + \lambda n$ and $q_j \in g$. Thus, $\lambda = c - \langle p_j, n\rangle = \langle q_0 - p_j, n\rangle$.

2.2.2 Minimum for fixed normal vector

We fix a normal vector $n \in S^1$ and define $f(c) := f(c, n)$. Now

$$f'(c) = 2\sum_{j=1}^{m}(c - \langle p_j, n\rangle) = 2mc - 2\left\langle \sum_{j=1}^{m} p_j, n \right\rangle, \quad f''(c) \equiv 2m > 0.$$

Thus, the function $f : \mathbb{R} \to \mathbb{R}$, $c \mapsto f(c)$, is strictly convex. Every local extremum is a global minimum. The equation $f'(c) = 0$ holds if and only if

$$c = \left\langle \frac{1}{m}\sum_{j=1}^{m} p_j, n \right\rangle = \langle \bar{p}, n\rangle \text{ where } \bar{p} = \frac{1}{m}\sum_{j=1}^{m} p_j. \tag{5}$$

For any fixed normal vector n the line which contains the center of mass $\bar{p}$ gives the minimum of $f : \mathbb{R} \to \mathbb{R}$, $c \mapsto f(c)$.

2.2.3 Elimination of the variable c

In order to find the minimum of the function $f : \mathbb{R}^2 \to \mathbb{R}$, $(c, n) \mapsto f(c, n)$, it is sufficient to investigate lines that contain the center of mass $\bar{p}$. We consider $f : S^1 \to \mathbb{R}^{\geq 0}$ defined by

$$n \mapsto f(\langle \bar{p}, n\rangle, n) = \sum_{j=1}^{m}\langle \bar{p} - p_j, n\rangle^2 = \sum_{j=1}^{m}\langle \tilde{p}_j, n\rangle^2 = \sum_{j=1}^{m}(\tilde{p}_j^T n)^2 \text{ where } \tilde{p}_j = \bar{p} - p_j.$$

The change of notation (from p_j to $\tilde{p}_j = (\tilde{x}_j, \tilde{y}_j)^T$) corresponds to the translation of the origin to the center of mass $\bar{p}$. The function $f(n)$ is even, i.e., $f(n) = f(-n)$ for all $n \in S^1$.

2.2.4 Optimal normal vector

We use the parametrization $n(t) = (\cos t, \sin t)^T$ and consider the function $h(t) := f(n(t))$. Since $\tilde{p}_j^T n = n^T \tilde{p}_j$ and

$$n'(t) = \begin{pmatrix} -\sin t \\ \cos t \end{pmatrix} = Jn(t) \text{ with } J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},$$

we obtain

$$\frac{dh}{dt} = 2\sum_{j=1}^{m} \tilde{p}_j^T n \tilde{p}_j^T \frac{dn}{dt} = 2\sum_{j=1}^{m} n^T \tilde{p}_j \tilde{p}_j^T Jn = 2n^T \left(\sum_{j=1}^{m} \tilde{p}_j \tilde{p}_j^T \right) Jn = 2n^T SJn$$

with

$$S = \sum_{j=1}^{m} \tilde{p}_j \tilde{p}_j^T = \begin{pmatrix} S_{xx} & S_{xy} \\ S_{xy} & S_{yy} \end{pmatrix}, \; S_{xx} = \sum_{j=1}^{m} \tilde{x}_j^2, \; S_{xy} = \sum_{j=1}^{m} \tilde{x}_j \tilde{y}_j, \; S_{yy} = \sum_{j=1}^{m} \tilde{y}_j^2. \tag{6}$$

It is easy to check that the matrix S is symmetric:

$$S^T = \left(\sum_{j=1}^{m} \tilde{p}_j \tilde{p}_j^T \right)^T = \sum_{j=1}^{m} \left(\tilde{p}_j \tilde{p}_j^T \right)^T = \sum_{j=1}^{m} \left(\tilde{p}_j^T \right)^T \tilde{p}_j^T = \sum_{j=1}^{m} \tilde{p}_j \tilde{p}_j^T = S$$

The fact $Jn \perp n$ yields $h'(t) = 0 \Leftrightarrow n \perp SJn \Leftrightarrow SJn = \lambda Jn$ for a $\lambda \in \mathbb{R}$. This means that Jn is an eigenvector of the matrix S. The symmetric matrix S is diagonalisible. The eigenspaces of S are perpendicular to each other. Thus, n is an eigenvector of S if and only if Jn is an eigenvector of S.

- If the matrix S has two different eigenvalues $\lambda_1 \neq \lambda_2$, then the associated normalized eigenvectors $\pm n_1$, $\pm n_2$ are the critical points of $f : n \mapsto f(n)$.
- If the matrix S has a two dimensional eigenspace, then $h'(t) \equiv 0$. Thus all lines through the center of mass are optimal.

Using the identity $J^2 = -\operatorname{Id}$ we derive

$$\begin{aligned} \frac{d^2h}{dt^2} = &= \frac{d}{dt}\left(2n^T SJn\right) = 2\left((SJn)^T \frac{dn}{dt} + n^T SJ\frac{dn}{dt} \right) \\ &= 2\left((Jn)^T S^T Jn + n^T SJJn\right) = 2\left((Jn)^T SJn - n^T Sn\right). \end{aligned}$$

Now,

$$h''(\pm n_1) = 2(\lambda_2 - \lambda_1) \text{ and } h''(\pm n_2) = 2(\lambda_1 - \lambda_2).$$

Therefore, the normalized eigenvectors of the smallest and the largest eigenvalue correspond to the local minima respectively maxima of $f(n)$. These local extrema are global, since $f(n)$ is symmetric.

Lemma 1. *Let E_- be the eigenspace of the smallest eigenvalue of S.*

- *$E_- = \mathbb{R}^2$ if and only if $S_{xy} = 0$ und $S_{xx} = S_{yy}$.*
- *$(1,0)^T \in E_-$ if and only if $S_{xy} = 0$ und $S_{xx} \leq S_{yy}$.*
- *If $(1,0)^T \notin E_-$, then $E_- = \mathbb{R}(a,-1)^T$ with*

$$a = \frac{2S_{xy}}{S_{xx} - S_{yy} + \sqrt{(S_{xx} - S_{yy})^2 + 4S_{xy}^2}}.$$

Proof. The vector $(1,0)^T$ is an eigenvector of S if and only if S is a diagonal matrix, i.e., $S_{xy} = 0$. Then $(1,0)^T$ and $(0,1)^T$ are eigenvectors of the eigenvalues S_{xx} respectively S_{yy}.

Let us calculate the eigenvalues of S:

$$\begin{aligned} 0 &= \det(S - \lambda \operatorname{Id}) = (S_{xx} - \lambda)(S_{yy} - \lambda) - S_{xy}^2 \\ &= \lambda^2 - \lambda (S_{xx} + S_{yy}) + S_{xx}S_{yy} - S_{xy}^2 \\ \lambda &= \frac{1}{2}(S_{xx} + S_{yy}) \pm \frac{1}{2}D \text{ with } D = \sqrt{(S_{xx} - S_{yy})^2 + 4S_{xy}^2} \end{aligned}$$

If $(1,0)^T \notin E_-$, then $\dim E_- = 1$ and $S_{xy} \neq 0$ or $S_{xx} > S_{yy}$. The general solution of the linear equation $(S - \lambda \operatorname{Id})v = 0$ with $\lambda = (S_{xx} + S_{yy} - D)/2$ is $v = t(a,-1)^T$ with $t \in \mathbb{R}$ and $a = 2S_{xy}/(S_{xx} - S_{yy} + D)$. ☐

Theorem 2. *Let $p_j \in \mathbb{R}^2$, $j = 1, \dots, m$, be pairwise distinct points. A line $g \subset \mathbb{R}^2$ has minimal geometric L^2-distance to the set $\{p_1, \dots, p_m\}$ if and only if $\bar{p} \in g$ and the eigenspace of the smallest eigenvalue of S contains a normal vector of g.*

- *If $S_{xy} = 0$ and $S_{xx} = S_{yy}$, then any line through $\bar{p}$ is optimal.*
- *If $S_{xy} = 0$ and $S_{xx} < S_{yy}$, then there exists a unique optimal line: $x = \bar{x}$*
- *If $S_{xy} \neq 0$ or $S_{xx} > S_{yy}$, then there exists a unique optimal line:*

$$y = \frac{2S_{xy}}{S_{xx} - S_{yy} + D}(x - \bar{x}) + \bar{y} \tag{7}$$

Proof. An optimal line with normal vector $(a,-1)^T$ can be parametrized by $g = \{\bar{p} + t(1,a)^T : t \in \mathbb{R}\}$. The slope of this line is a. ☐

Corollary 2. *If the point set $\{p_1, \dots, p_m\}$ is invariant under reflection in a line $g \ni \bar{p}$, then this line g or the line perpendicular to g containing $\bar{p}$ is a line with minimal geometric L^2-distance to the set $\{p_1, \dots, p_m\}$.*

Proof. Let $l \neq g$ be an optimal line that contains $\bar{p}$ and is not perpendicular to g. Since l is not invariant under the reflection in g, there exist at least two optimal lines. Thus, all lines containing $\bar{p}$ are optimal. ☐

Corollary 3. *If the point set* $\{p_1, \ldots, p_m\}$ *is invariant under a rotation around* $\bar{p}$ *through an angle* $\phi \notin \mathbb{Z}\pi$*, then* $S_{xy} = 0$ *and* $S_{xx} = S_{yy}$*.*

Proof. Since $\phi \neq k\pi$ for all $k \in \mathbb{Z}$, no line is invariant under the rotation. Thus, all lines containing $\bar{p}$ are optimal. □

Remark 2. Theorem 2 and its corollaries remain true if the points $p_1, \ldots, p_m$ are not pairwise distinct.

2.2.5 Generalizations

A natural generalization of the subject in this section is an affine subspace of fixed dimension $k < n$ with minimal geometric L^2-distance to a given finite set in $\mathbb{R}^n$. The corresponding optimal lines and planes in $\mathbb{R}^3$ are discussed in [6]. For $k = n - 1$ this problem leads to overdetermined systems of linear equations that can be treated with total least squares (TLS) techniques. In this section the essential information about the point set is stored in the matrix S. The decomposition of a similar matrix S reappears in a method of multivariate statistics called principal component analysis (PCA).

2.3 Example an comparison algebraic versus geometric

Any L^2-optimal line contains the center of mass of the set $\{p_1, \ldots, p_m\}$. The algebraic problem always possesses a unique solution. The geometric problem admits a unique solution that is a graph of a linear function if and only if $S_{xy} \neq 0$ or $S_{xx} > S_{yy}$.

Theorem 3. *The algebraic and the geometric* L^2*-optimal lines coincide if and only if this line contains all points* p_j *or* $S_{xy} = 0$ *and* $S_{xx} \geq S_{yy}$*.*

Proof. If $S_{xy} = 0$ and $S_{xx} > S_{yy}$, then the algebraic and the geometric L^2-optimal lines coincide if and only if

$$\frac{S_{xy}}{S_{xx}} = \frac{2S_{xy}}{S_{xx} - S_{yy} + D}.$$

This equation holds if and only if $S_{xy} = 0$ or

$$\begin{aligned} S_{xx} - S_{yy} + D &= 2S_{xx} \\ D &= S_{xx} + S_{yy} \\ (S_{xx} - S_{yy})^2 + 4S_{xy} &= (S_{xx} + S_{yy})^2 \\ S_{xx}S_{yy} &= S_{xy}. \end{aligned}$$

It follows from the Schwarz inequality that

$$S_{xx}S_{yy} = \sum_{j=1}^{m} \tilde{x}_j^2 \sum_{j=1}^{m} \tilde{y}_j^2 \geq (\sum_{j=1}^{m} \tilde{x}_j \tilde{y}_j)^2 = S_{xy}^2,$$

where equality holds if and only if $\lambda \tilde{x}_j = \tilde{y}_j$ for a $\lambda \in \mathbb{R}$ and all j. □

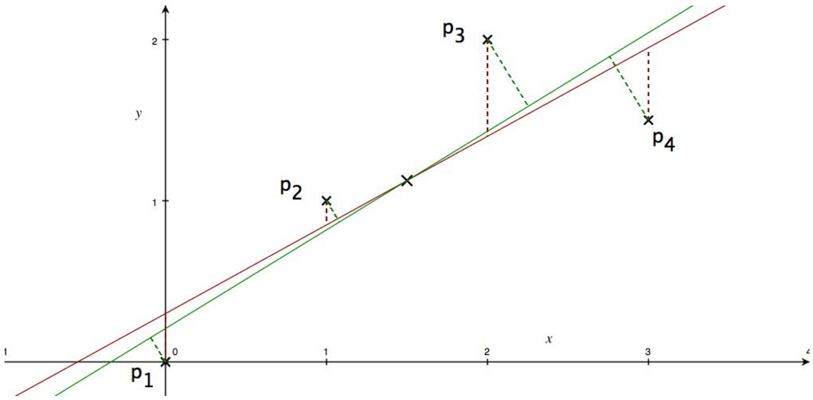

Figure 1: vertical and orthogonal L^2-optimal lines

We consider the four points $p_1 = (0,0)^T$, $p_2 = (1,1)^T$, $p_3 = (2,2)^T$ and $p_4 = (3,3/2)^T$ (see Figure 1). Their center of mass is $\bar{p} = (3/2, 9/8)^T$. Now, $\tilde{p}_1 = (-3/2, -9/8)^T$, $\tilde{p}_2 = (-1/2, -1/8)^T$, $\tilde{p}_3 = (1/2, 7/8)^T$, $\tilde{p}_4 = (3/2, 3/8)^T$, $S_{xx} = 5$, $S_{yy} = 35/16$ und $S_{xy} = 11/4$. The algebraic L^2-optimal linear function is

$$y(x) = a\left(x - \frac{3}{2}\right) + \frac{9}{8} \text{ with } a = \frac{11}{20} = 0.55.$$

The geometric L^2-optimal line is the graph of the linear function

$$y(x) = a\left(x - \frac{3}{2}\right) + \frac{9}{8} \text{ with } a = \frac{88}{45 + \sqrt{45^2 + 88^2}} \approx 0.61.$$

The algebraic and the geometric L^2-optimal lines intersect at $\bar{p}$.

3 Absolute distance - L^1-Norm

In this section we minimize the sum of the distances of the single points p_j. We consider the function $f(g) = \sum_{j=1}^{m} d_j$. This function is differentiable at g if and only if $d_j > 0$ for all j, i.e., g contains none of the points p_j. We prove that there exists a global minimum of f for the algebraic and the geometric distance. The set of all L^1-optimal lines is described. Explicit formulas of the elements of M in terms of $p_1, \dots, p_m$ are not available, yet the set M can be completely characterized by comparing the values of f at lines containing at least two of the points p_j. Minimizing the L^1-norm can be carried out in $\leq O(m^2)$ steps.

3.1 Minimal algebraic L^1-distance

Given points $p_j = (x_j, y_j)^T \in \mathbb{R}^2$, $j = 1, \dots, m$, we determine all linear functions $y(x) = ax + b$, $a, b \in \mathbb{R}$, with minimal algebraic L^1-distance to the point set

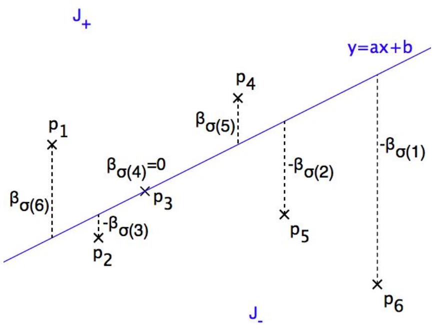

Figure 2: algebraic decomposition of the index set, definition of $\beta_{\sigma(j)}$

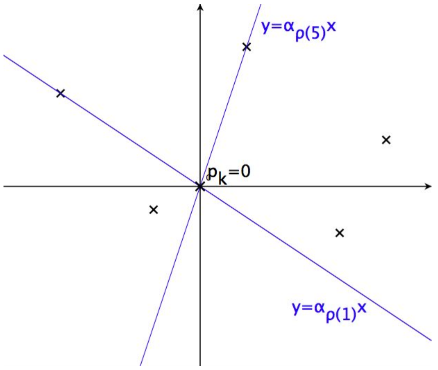

Figure 3: definition of $\alpha_{\sigma(j)}$ for lines through p_k

$\{p_1, \ldots, p_m\}$, i.e., the minimum of the function $f : \mathbb{R}^2 \to \mathbb{R}$ defined by

$$f(a, b) = \sum_{j=1}^{m} |y_j - (ax_j + b)|.$$

As in subsection 2.1 we additionally assume that $x_j \neq x_k$ for all $j \neq k$.

The function f is continuous, piecewise linear, convex and bounded from below. Thus, f admits a global minimum. The set of algebraically L^1-optimal lines M is convex. Since f is not strictly convex, the set M could be unbounded. We show that M is the convex hull of finitely many points.

3.1.1 Decomposition of the index set

For every linear function $y(x) = ax + b$ we define $J_+ := \{j : y_j > y(x_j)\}$, $J_0 := \{j : y_j = y(x_j)\}$ und $J_- := \{j : y_j < y(x_j)\}$. This decomposition depends on the parameters a and b (see Figure 2). The sets J_+, J_0 and J_- are pairwise disjoint, $J_+ \cup J_0 \cup J_- = \{1, \ldots, m\}$ and

$$\begin{aligned} f(a, b) &= \sum_{j \in J_+} (y_j - ax_j - b) - \sum_{j \in J_-} (y_j - ax_j - b) \\ &= b(|J_-| - |J_+|) + \left(\sum_{j \in J_+} y_j - \sum_{j \in J_-} y_j \right) - a \left(\sum_{j \in J_+} x_j - \sum_{j \in J_-} x_j \right). \end{aligned}$$

3.1.2 Translation

For any $a \in \mathbb{R}$ we consider the values of f at lines with fixed slope a and variable b. We want to determine the optimal line with slope a, i.e., $\min\{f(a, b) : b \in \mathbb{R}\}$.

Note that $f(a, 0) = \sum_{j=1}^{m} |y_j - ax_j|$. Set $\beta_j := y_j - ax_j$. Let σ be a permutation satisfying $\beta_{\sigma(1)} \leq \ldots \leq \beta_{\sigma(m)}$ (see Figure 2).

Lemma 2. *For every* $a \in \mathbb{R}$ *the function* $f(a,\cdot) : \mathbb{R} \to \mathbb{R}$, $b \mapsto f(a,b)$ *admits a global minimum. If* $f(a,b_0) = \min\{f(a,b) : b \in \mathbb{R}\}$, *then* $\beta_{\sigma(1)} \leq b_0 \leq \beta_{\sigma(m)}$.

Proof. If $b > \beta_{\sigma(m)}$, then $J_+ = J_0 = \emptyset$. If $b < \beta_{\sigma(1)}$, then $J_- = J_0 = \emptyset$. Consequently,

$$f(a,b) = mb - \sum_{j=1}^{m} y_j + a \sum_{j=1}^{m} x_j \text{ for } b > \beta_{\sigma(m)}$$

and

$$f(a,b) = -mb + \sum_{j=1}^{m} y_j - a \sum_{j=1}^{m} x_j \text{ for } b < \beta_{\sigma(1)}.$$

The function $f(b)$ is strictly decreasing for $b < \beta_{\sigma(1)}$ and strictly increasing for $b > \beta_{\sigma(m)}$. Continuity of f yields

$$\inf_{b \in \mathbb{R}} f(a,b) = \inf_{\beta_\sigma(1) \leq b \leq \beta_{\sigma(m)}} f(a,b) = \min_{\beta_{\sigma(1)} \leq b \leq \beta_{\sigma(m)}} f(a,b).$$

□

Lemma 3. *For every* $a \in \mathbb{R}$ *the function* $f(a,\cdot)$ *admits its global minimum at* b *if and only if* $|J_-| + |J_0| - |J_+| \geq 0$ *und* $|J_+| + |J_0| - |J_-| \geq 0$.

For every $a \in \mathbb{R}$ *the function* $f(a,\cdot)$ *admits its strict global minimum at* b *if and only if* $|J_-| + |J_0| - |J_+| > 0$ *und* $|J_+| + |J_0| - |J_-| > 0$.

Proof. Let J_+, J_0, J_- be the decomposition of the index set of the function $y(x) = ax + b$. If $\max\{\beta_j - b : j \in J_-\} < \varepsilon < \min\{\beta_j - b : j \in J_+\}$, then the decomposition of the index set of the function $ax + b + \varepsilon$ is equal to the decomposition of $ax + b$. Now

$$\begin{aligned} f(a,b+\varepsilon) &= \sum_{j \in J_+} (y_j - ax_j - b - \varepsilon) - \sum_{j \in J_-} (y_j - ax_j - b - \varepsilon) + \sum_{j \in J_0} |\varepsilon| \\ &= f(a,b) + \varepsilon \cdot \begin{cases} |J_-| + |J_0| - |J_+| & \text{if } \varepsilon > 0 \\ |J_-| - |J_0| - |J_+| & \text{if } \varepsilon < 0 \end{cases}. \end{aligned}$$

□

Corollary 4. *For every* $a \in \mathbb{R}$ *the function* $f(a,\cdot)$ *admits its global minimum at* b *if and only if* $||J_+| - |J_-|| \leq |J_0|$.
Furthermore, $\min\{f(a,b) : b \in \mathbb{R}\} = f(a,b_0)$ *if and only if* $\beta_k \leq b_0 \leq \beta_l$ *with*

$$k = \left\lfloor \frac{m+1}{2} \right\rfloor, \, l = \left\lceil \frac{m+1}{2} \right\rceil.$$

Proof. The inequalities $|J_-| + |J_0| - |J_+| \geq 0$ and $|J_+| + |J_0| - |J_-| \geq 0$ are both satisfied if and only if $|J_0| \geq ||J_+| - |J_-||$.

If $\beta_k \leq b \leq \beta_l$, then

- $|J_-| + |J_0| \geq k$, $|J_+| \leq m - k \leq |J_-| + |J_0|$, since $2k \geq m$.
- $|J_+| + |J_0| \geq m - l + 1$, $|J_-| \leq l - 1 \leq |J_+| + |J_0|$, since $2(l-1) \leq m$.

If $b < \beta_k$, then $|J_-| + |J_0| \leq k - 1$ and $|J_+| \geq m - (k-1) > |J_-| + |J_0|$, since $2(k-1) < m$.

If $b > \beta_l$, then $|J_+| + |J_0| \leq m - l$ and $|J_-| \geq l > |J_+| + |J_0|$, since $2l > m$. ☐

Corollary 5. *Among all optimal lines with fixed slope $a \in \mathbb{R}$ there exists at least one that contains one of the points p_j.*

Proof. If $b = \beta_k$ or $b = \beta_l$, then $J_0 \neq \emptyset$. ☐

3.1.3 Rotation

For every point p_k we consider the values of f at lines containing p_k. These lines are obtained by rotating one of them around p_k. The condition $y(x_k) = y_k$ implies $b = y_k - a x_k$. For any fixed index k we investigate the function $f : \mathbb{R} \to \mathbb{R}$ defined by

$$\begin{aligned} f(a) := f(a, y_k - a x_k) &= \sum_{j=1}^{m} |y_j - a x_j - (y_k - a x_k)| \\ &= \sum_{j=1}^{m} |(y_j - y_k) - a(x_j - x_k)| = \sum_{j \neq k} |\tilde{y}_j - a \tilde{x}_j| \end{aligned}$$

with $\tilde{y}_j := y_j - y_k$ and $\tilde{x}_j := x_j - x_k$.

The coordinate change $(x_j, y_j) \to (\tilde{x}_j, \tilde{y}_j)$ corresponds to the translation of the origin to the center of the rotation. The decomposition of the index set is now given by $J_- = \{j : \tilde{y}_j < a\tilde{x}_j\}$, $J_0 = \{j : \tilde{y}_j = a\tilde{x}_j\} \ni k$ and $J_+ = \{j : \tilde{y}_j > a\tilde{x}_j\}$. It follows

$$f(a) = \sum_{j \in J_+} \tilde{y}_j - \sum_{j \in J_-} \tilde{y}_j - a \left(\sum_{j \in J_+} \tilde{x}_j - \sum_{j \in J_-} \tilde{x}_j \right).$$

Set $\alpha_j := \tilde{y}_j / \tilde{x}_j$ for $j \neq k$. Let τ be a permutation satisfying $\tau(m) = k$ and $\alpha_{\tau(1)} \leq \ldots \leq \alpha_{\tau(m-1)}$ (see Figure 3).

Lemma 4. *The function $f : a \mapsto f(a)$ admits a global minimum. If $f(a_0) = \min\{f(a) : a \in \mathbb{R}\}$, then $\alpha_{\tau(1)} \leq a_0 \leq \alpha_{\tau(m-1)}$.*

Proof. If $a > \alpha_{\tau(m-1)}$, then $J_0 = \{k\}$, $J_+ = \{j : \tilde{x}_j < 0\}$, $J_- = \{j : \tilde{x}_j > 0\}$ and $f'(a) = \sum_{j \in J_-} \tilde{x}_j - \sum_{j \in J_+} \tilde{x}_j > 0$.

If $a < \alpha_{\tau(1)}$, then $J_0 = \{k\}$, $J_+ = \{j : \tilde{x}_j > 0\}$, $J_- = \{j : \tilde{x}_j < 0\}$ and $f'(a) = \sum_{j \in J_-} \tilde{x}_j - \sum_{j \in J_+} \tilde{x}_j > 0$.

Continuity of f yields

$$\inf_{a \in \mathbb{R}} f(a) = \inf_{\alpha_{\tau(1)} \leq a \leq \alpha_{\tau(m-1)}} f(a) = \min_{\alpha_{\tau(1)} \leq a \leq \alpha_{\tau(m-1)}} f(a).$$

☐

Corollary 6. *The function* $f : \mathbb{R}^2 \to \mathbb{R}$ *defined by* $f(a,b) = \sum_{j=1}^{m} |y_j - ax_j - b|$ *admits a global minimum. This global minimum is attained at a bounded set.*

Proof. If $f(a,b)$ is a global minimum of f, then $a_0 \leq a \leq a_1$ and $b_0 \leq b \leq b_1$ where

$$a_0 = \min_{j \neq k} \frac{y_j - y_k}{x_j - x_k},\ a_1 = \max_{j \neq k} \frac{y_j - y_k}{x_j - x_k},\ b_0 = \min_{i,j} y_j - a_i x_j,\ b_1 = \max_{i,j} y_j - a_i x_j.$$

□

Lemma 5. *For every index* k *holds* $\min\{f(a) : a \in \mathbb{R}\} = \min\{f(\alpha_j) : j \neq k\}$.

Proof. If $J_0 = \{k\}$, then f is differentiable at the line corresponding to that decomposition. Note that $J_0 = \{k\}$ if and only if $a \neq \alpha_j$ for all $j \neq k$. If $f'(a) = 0$ for $a \in \mathbb{R}$ with $a_{\sigma(k)} < a < a_{\sigma(k+1)}$, then f is constant on the interval $[a_{\sigma(k)}, a_{\sigma(k+1)}]$. □

3.1.4 The set of optimal lines

Corollary 5 and Lemma 5 imply the existence of a line containing at least two $p_j \neq p_k$ among all lines with minimal algebraic L^1-distance to the set $\{p_1, \ldots, p_m\}$. There are $\leq m(m-1)/2$ lines with this property. It is sufficient to check the lines that additionally satisfy $||J_+| - |J_-|| \leq |J_0|$ to find the minimum of f.

The line which contains the two points p_j and p_k with $j \neq k$ is called g_{jk}. The line g_{jk} is the graph of the linear function $y(x) = a_{jk}x + b_{jk}$ with

$$a_{jk} = \frac{y_j - y_k}{x_j - x_k} \text{ and } b_{jk} = \frac{y_k x_j - y_j x_k}{x_j - x_k}. \tag{8}$$

The line g_{jk} corresponds to a point in the domain of definition $\{(a,b) : a, b \in \mathbb{R}\}$ of the function f. This point (a,b) is the unique solution of the two equations $y_j = ax_j + b$ and $y_k = ax_k + b$, since $x_j \neq x_k$. We denote this point of intersection by g_{jk} too, i.e., $g_{jk} = (a_{jk}, b_{jk})$. Let E be the set of optimal lines containing at least two of the points p_j. More precisely,

$$E := \{g_{jk} : j > k \text{ and } f(a_{jk}, b_{jk}) = \min\{f(a,b) : a, b \in \mathbb{R}^2\}\}. \tag{9}$$

Theorem 4. *Let* $p_j = (x_j, y_j)^T$, $j = 1, \ldots, m$, *such that* $x_j \neq x_k$ *for all* $j \neq k$. *A linear function* $y(x) = ax + b$ *has minimal algebraic* L^1*-distance to the set* $\{p_1, \ldots, p_m\}$ *if and only if* (a,b) *is contained in the convex hull of* E.

Proof. If $f(a_0, b_0)$ is the global minimum of f and $y_k = a_0 x_k + b_0$ for exactly one index $1 \leq k \leq m$, then Lemma 5 implies the existence of indices $1 \leq j_1, j_2 \leq m$ satisfying $j_1, j_2 \neq k$ and $f(g_{j_1 k}) = f(g_{j_2 k}) = f(a_0, b_0)$. Consequently, the point (a_0, b_0) lies on the line $y_k = ax_k + b$ between the points $g_{j_1 k}, g_{j_2 k} \in E$.

If $f(a_0, b_0)$ is the global minimum of f and $y_j \neq a_0 x_j + b_0$ for all j, then Corollary 4 implies the existence if indices k, l satisfying $f(a_0, b_0) = f(a_0, b)$ for all $b_k := y_k - a_0 x_k \leq b \leq y_l - a_0 y_l =: b_l$. Since $f(a_0, b_k) = f(a_0, b_l)$ is the global minimum of f and the lines corresponding to (a_0, b_k) and (a_0, b_l) contain the point p_k respectively p_l, the points (a_0, b_k) and (a_0, b_l) are contained in the convex hull of E. Now (a_0, b_0) is a point of the line segment from (a_0, b_k) to (a_0, b_l). Therefore, (a_0, b_0) is in the convex hull of E. □

Remark 3. With a small change in the definition of E Theorem 4 remains true, if the condition $x_j \neq x_k$ for all $j \neq k$ is weakened to existence of indices $j \neq k$ satisfying $x_j \neq x_k$. This weaker assumption is sufficient to bound interesting slopes using Lemma 4, because $\alpha_j \neq \pm\infty$ for at least on index j. To adjust the definition of E we then regard only lines g_{jk} with $x_j \neq x_k$.

However, if $x_1 = \ldots = x_m = \bar{x}$, then any graph of a linear function contains at most one of the points p_j. This would mean that $E = \emptyset$. But note that the algebraic distances between the points p_j and the linear function $y(x) = a(x - \bar{x}) + b$ are independent of the variable a. We substitute the set E by the set $B := \{y_k : f(0, y_k) = \min\{f(0, y_j) : j = 1, \ldots, m\}\} \subset \mathbb{R}$. Now, $y(x) = a(x - \bar{x}) + b$ is an algebraically L^1-optimal linear function if and only if b is contained in the convex hull of B.

3.1.5 Examples

Three points: We show the existence of a unique linear function with minimal algebraic L^1-distance to three given pairwise distinct points. Let $x_1 < x_2 < x_3$ and $y_1, y_2, y_3 \in \mathbb{R}$. There exists a line containing all three points $(x_j, y_j)^T$ if and only if $(y_2 - y_1)/(x_2 - x_1) = (y_3 - y_1)/(x_3 - x_1)$.

If $(y_2 - y_1)/(x_2 - x_1) \neq (y_3 - y_1)/(x_3 - x_1)$, then

$$\begin{aligned}
f(g_{31}) &= \left| y_2 - \frac{y_3 - y_1}{x_3 - x_1}(x_2 - x_1) - y_1 \right| \\
&= \frac{|(y_2 - y_1)(x_3 - x_1) - (y_3 - y_1)(x_2 - x_1)|}{x_3 - x_1} \\
&= \frac{|(y_2 - y_1)(x_3 - x_2) - (y_3 - y_2)(x_2 - x_1)|}{x_3 - x_1} \\
f(g_{21}) &= \left| y_3 - \frac{y_2 - y_1}{x_2 - x_1}(x_3 - x_1) - y_1 \right| \\
&= \frac{|(y_3 - y_1)(x_2 - x_1) - (y_2 - y_1)(x_3 - x_1)|}{x_2 - x_1} > f(g_{31}) \\
f(g_{32}) &= \left| y_1 - \frac{y_3 - y_2}{x_3 - x_2}(x_1 - x_2) - y_2 \right| \\
&= \frac{|(y_1 - y_2)(x_3 - x_2) - (y_3 - y_2)(x_1 - x_2)|}{x_3 - x_2} > f(g_{31})
\end{aligned}$$

because $x_3 - x_1 > x_2 - x_1$ and $x_3 - x_1 > x_3 - x_2$. There is a unique line with minimal algebraic L^1-distance to $\{p_1, p_2, p_3\}$. It is the line through p_1 and p_3.

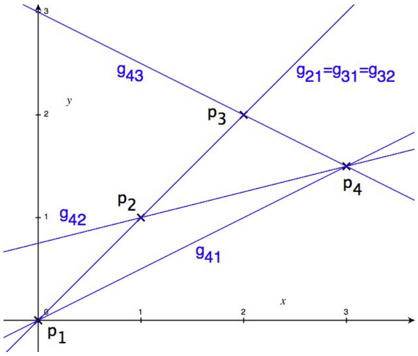

Figure 4:

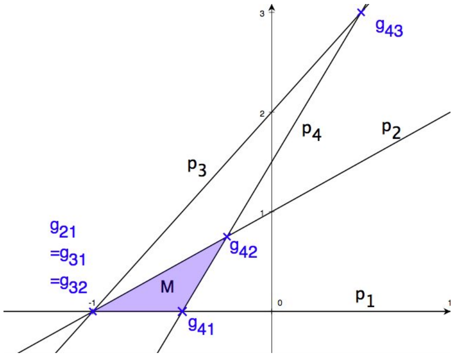

Figure 5:

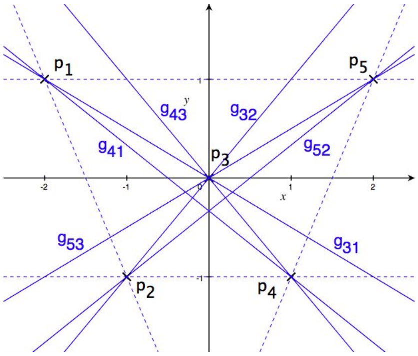

Figure 6:

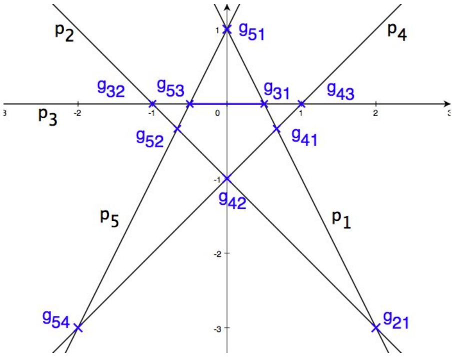

Figure 7:

Family of optimal lines for $m = 4$: We consider the points $p_1 = (0,0)^T$, $p_2 = (1,1)^T$, $p_3 = (2,2)^T$ and $p_4 = (3,3/2)^T$ (see Figure 4). Note that $g_{21} = g_{31} = g_{32}$, because the three points p_1, p_2 and p_3 are collinear. Now $f(g_{21}) = 3/2$, $f(g_{43}) = 9/2$, $f(g_{42}) = 3/2$, $f(g_{41}) = 3/2$. Thus, the set M of optimal lines is the convex hull of $g_{21} = g_{31} = g_{32}$, g_{41} and g_{42} (see Figure 5).

Invariance under reflection for $m = 5$: Let us consider the five points $p_1 = (-2,1)^T$, $p_2 = (-1,-1)^T$, $p_3 = (0,0)^T$, $p_4 = (1,-1)^T$ and $p_5 = (2,1)^T$ (see Figure 6). This set is symmetric with respect to the reflection in the y-axis. Hence, the set M is invariant under this reflection. The lines g_{51}, g_{21}, g_{42} and g_{54} appear as dotted lines in Figure 6, because they do not satisfy the condition $||J_+| - |J_-|| \leq |J_0|$. Now $f(g_{31}) = f(g_{53}) = 4$, $f(g_{32}) = f(g_{43}) = 6$ and $f(g_{41}) = f(g_{52}) = 13/3 > 4$.

The set M of optimal lines is the line segment from g_{53} to g_{31} in Figure 7. The elements of M correspond to the functions $y(x) = ax$ with $-1/2 \leq a \leq 1/2$.

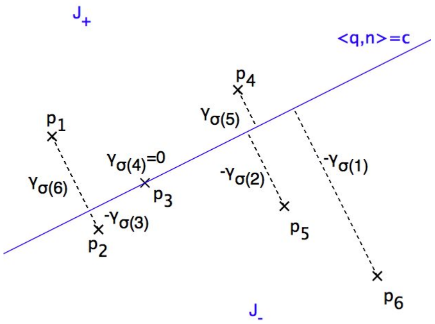

Figure 8: geometric decomposition of the index set, definition of $\gamma_{\sigma(j)}$

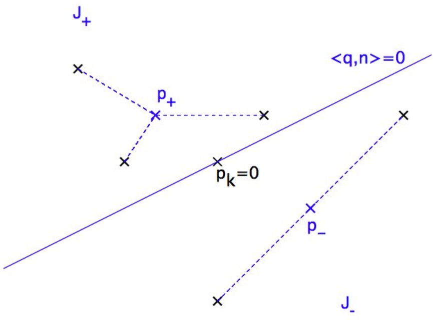

Figure 9: definition of p_+ and p_- for lines through p_k

3.2 Minimal geometric L^1-distance

Given pairwise distinct points $p_j \in \mathbb{R}^2$, $j = 1, \dots, m$, we determine lines described as $g = \{q \in \mathbb{R}^2 : c = \langle q, n\rangle\}$, $c \in \mathbb{R}$, $n \in S^1$ with minimal geometric L^1-distance to the point set $\{p_1, \dots, p_m\}$, i.e., the minimum of the function $f : \mathbb{R} \times S^1 \to \mathbb{R}$ defined by

$$f(c, n) = \sum_{j=1}^{m} |c - \langle p_j, n\rangle|.$$

Similar to the definitions in subsection 3.1.1 we decompose the index set. For every line $\{q \in \mathbb{R}^2 : \langle q, n\rangle = c\}$ set $J_+ := \{j : \langle p_j, n\rangle > c\}$, $J_0 := \{j : \langle p_j, n\rangle = c\}$ and $J_- := \{j : \langle p_j, n\rangle < c\}$ (see Figure 8). Now

$$\begin{aligned} f(c, n) &= \sum_{j \in J_-} (c - \langle p_j, n\rangle) + \sum_{j \in J_+} (\langle p_j, n\rangle - c) \\ &= c(|J_-| - |J_+|) - \sum_{j \in J_-} \langle p_j, n\rangle + \sum_{j \in J_+} \langle p_j, n\rangle. \end{aligned}$$

3.2.1 Translation

For any $n \in S^1$ we restrict f to lines with fixed normal vector n. We want to determine the optimal line with normal vector n, i.e., $\min\{f(c, n) : c \in \mathbb{R}\}$. Set $\gamma_j := \langle p_j, n\rangle$ and let σ be a permutation satisfying $\gamma_{\sigma(1)} \le \dots \le \gamma_{\sigma(m)}$ (see Figure 8).

Lemma 6. *For every $n \in S^1$ the function $f : \mathbb{R} \to \mathbb{R}$, $c \mapsto f(c, n)$, admits a global minimum. If $\min\{f(c, n) : c \in \mathbb{R}\} = f(c_0, n)$, then $\gamma_{\sigma(1)} \le c_0 \le \gamma_{\sigma(m)}$.*

Proof. The function $f : c \mapsto f(c, n)$ is continuous, piecewise linear and convex. If $J_0 = \emptyset$, then f is differentiable and $f'(c) = |J_-| - |J_+|$.

If $c > \gamma_{\sigma(m)}$, then $J_0 = J_+ = \emptyset$ and $f'(c) = m > 0$. If $c < \gamma_{\sigma(1)}$, then $J_0 = J_- = \emptyset$ and $f'(c) = -m < 0$. Continuity of f yields

$$\inf_{c\in\mathbb{R}} f(c) = \inf\{f(c) : \gamma_{\sigma(1)} \leq c \leq \gamma_{\sigma(m)}\} = \min\{f(c) : \gamma_{\sigma(1)} \leq c \leq \gamma_{\sigma(m)}\}.$$

□

Lemma 7. *For every $n \in S^1$ the value $f(c, n)$ is a local minimum of the function $f(\cdot, n)$ if and only if $|J_-| + |J_0| - |J_+| \geq 0$ and $|J_+| + |J_0| - |J_-| \geq 0$. A local minimum is strict if and only if $|J_-|+|J_0|-|J_+| > 0$ and $|J_+|+|J_0|-|J_-| > 0$.*

Proof. Let J_+, J_0, J_- be the decomposition of the index set for the line $\langle q, n\rangle = c$. If $\max\{\gamma_j - c : j \in J_-\} < \varepsilon < \min\{\gamma_j - c : j \in J_+\}$, then the decomposition of the index set for the line $\langle q, n\rangle = c + \varepsilon$ is equal to that for $\langle q, n\rangle = c$ and

$$\begin{aligned} f(c+\varepsilon, n) &= (|J_-| - |J_+|)(c + \varepsilon) - \sum_{j\in J_-} \langle p_j, n\rangle + \sum_{j\in J_+} \langle p_j, n\rangle. + \sum_{j\in J_0} |\varepsilon| \\ &= f(c, n) + \varepsilon \cdot \begin{cases} |J_-| + |J_0| - |J_+| & \text{if } \varepsilon > 0 \\ |J_-| - |J_0| - |J_+| & \text{if } \varepsilon < 0 \end{cases}. \end{aligned}$$

□

Corollary 7. *For every $n \in S^1$ the value $f(c, n)$ is a global minimum of the function $f(\cdot, n)$ if and only if $||J_+| - |J_-|| \leq |J_0|$.*
Furthermore, $\min\{f(c) : c \in \mathbb{R}\} = f(c_0)$ *if and only if* $\gamma_k \leq c_0 \leq \gamma_l$ *with*

$$k = \left\lfloor \frac{m+1}{2} \right\rfloor, \, l = \left\lceil \frac{m+1}{2} \right\rceil.$$

Proof. Replace β by γ in the proof of Corollary 4. □

Corollary 8. *Among all optimal lines with fixed normal vector n there exists at least one containing one of the points p_j.*

Proof. If $b = \gamma_k$ and $b = \gamma_l$, then $J_0 \neq \emptyset$. □

Corollary 9. *The function $f : \mathbb{R}\times S^1 \to \mathbb{R}^{\geq 0}$ defined by $(c, n) \mapsto f(c, n)$ admits a global minimum.*

Proof. Since the function f is continuous and the set S^1 is compact, we obtain $\inf\{f(c, n) : c \in \mathbb{R}, n \in S^1\} = \min\{f(\langle p_j, n\rangle, n) : n \in S^1, j = 1, \ldots, m\}$. □

3.2.2 Rotation

For every point p_k we restrict f to lines containing p_k. The normal vector of the lines is variable, but the condition $p_k \in \{q \in \mathbb{R}^2 : c = \langle q, n\rangle\}$ implies $c = \langle p_k, n\rangle$. We investigate the function $f : S^1 \to \mathbb{R}$ given by

$$f(n) := f(\langle p_k, n\rangle, n) = \sum_{j=1}^{m} |\langle p_j, n\rangle - \langle p_k, n\rangle| = \sum_{j=1}^{m} |\langle p_j - p_k, n\rangle| = \sum_{j\neq k} |\langle \tilde{p}_j, n\rangle|,$$

where $\tilde{p_j} := p_j - p_k \neq 0$ for all $j \neq k$.

As before, the change of coordinates $p_j \mapsto \tilde{p_j}$ corresponds to the translation of the origin to p_k. For any normal vector $n \in S^1$ the decomposition of the index set with respect to the new coordinates is given by $J_+ = \{\langle \tilde{p_j}, n\rangle > 0\}$, $J_0 = \{\langle \tilde{p_j}, n\rangle = 0\} \ni k$ and $J_- = \{\langle \tilde{p_j}, n\rangle < 0\}$ (see Figure 9). Now

$$f(n) = \sum_{j\in J_+} \langle \tilde{p_j}, n\rangle - \sum_{j\in J_-} \langle \tilde{p_j}, n\rangle = \langle \tilde{p}, n\rangle \text{ where } \tilde{p} := \sum_{j\in J_+} \tilde{p_j} - \sum_{j\in J_-} \tilde{p_j}.$$

Lemma 8. *If $\langle \tilde{p_j}, n_0\rangle \neq 0$ for all $j \neq k$, then* $\min\{f(n) : n \in S^1\} < f(n_0)$.

Proof. Note that $\tilde{p}_k = 0$. Hence, $|J_0| \geq 1$. If $J_+ \cup J_- \neq \emptyset$, i.e., $\langle \tilde{p_j}, n\rangle \neq 0$ for at least one index $j \neq k$, then $f(n) = \langle \tilde{p}, n\rangle > 0$. Thus, $\tilde{p} \neq 0$.

Using the parametrization $n(t) = (\cos t, \sin t)^T$ of S^1 as in subsection 2.2.4 we define the function $h(t) := f(n(t))$. If $\langle p_j, n\rangle \neq 0$ for all $j \neq k$, i.e., $J_0 = \{k\}$, then f is differentiable at the corresponding point. Now

$$\frac{dh}{dt} = \tilde{p}^T Jn = \langle \tilde{p}, Jn\rangle, \quad h''(t) = \tilde{p}^T JJn(t) = -\tilde{p}^T n(t) = \langle -\tilde{p}, n(t)\rangle.$$

If $f(n(t))$ is a local extremum of f and $J_0 = \{k\}$, then there exists $\lambda \neq 0$ such that $\tilde{p} = \lambda n$, since $h'(t) = 0$ an $Jn \perp n$. A local extremum $f(n(t)))$ of f satisfying $J_0 = \{k\}$ is a local minimum if and only if $\lambda < 0$, since $h''(t) = -\lambda\langle n, n\rangle = -\lambda$. Set $\tilde{p}_+ := \sum_{j\in J_+} p_j$ and $\tilde{p}_- := \sum_{j\in J_-} p_j$. Note that $\tilde{p}_+ - \tilde{p}_- = \tilde{p}$, $\langle \tilde{p}_+, n\rangle > 0$ and $\langle \tilde{p}_-, n\rangle < 0$. This implies $\langle \tilde{p}_+, \lambda n\rangle < 0$, $\langle \tilde{p}_-, \lambda n\rangle > 0$. Thus, $\langle \tilde{p}_+ - \tilde{p}_-, \lambda n\rangle < 0$ contradicting $\langle \tilde{p}_+ - \tilde{p}_-, \lambda n\rangle = \langle \tilde{p}, \tilde{p}\rangle = \|\tilde{p}\|^2 > 0$. ☐

3.2.3 Summary of the geometric L^1-distance

Corollary 7 and Lemma 8 imply the existence of a line containing two of the points p_j among all lines with minimal geometric L^1-distance to the set $\{p_1, \ldots, p_m\}$. These are at most $m(m-1)/2$ lines. As in section 3.1, it is sufficient to check the lines which additionally satisfy $||J_+| - |J_-|| \leq |J_0|$.

As before, we denote the line through p_j and p_k with $j > k$ by g_{jk}. The normal vector of g_{jk} is $n_{jk} := J(p_j - p_k)\|p_j - p_k\|^{-1}$. The line g_{jk} is given by the equation $\langle q, n_{jk}\rangle = \langle p_k, n_{jk}\rangle =: c_{jk}$. Let E be the set of points in the domain f corresponding to optimal lines. More precisely,

$$E := \left\{ \pm (c_{jk}, n_{jk}) : f(c_{jk}, n_{jk}) = \min\{f(c, n) : c \in \mathbb{R}, n \in S^1\}\right\}. \tag{10}$$

Since $f : \mathbb{R} \times S^1 \to \mathbb{R}$ is only convex with respect to c, we perform the convex hull only in one direction and define

$$\bar{E} := \{(c, n) \in \mathbb{R} \times S^1 : \exists t \in [0, 1], (c_0, n), (c_1, n) \in E : c = tc_0 + (1-t)c_1\}. \tag{11}$$

Theorem 5. *Let $p_j \in \mathbb{R}^2$, $j = 1, \ldots, m$, be pairwise distinct points.*
The line defined by the equation $\langle q, n\rangle = c$ with $n \in S^1$ and $c \in \mathbb{R}$ has minimal geometric L^1-distance to the set $\{p_1, \ldots, p_m\}$ if and only if $(c, n) \in \bar{E}$.

Proof. The statement is a consequence of Corollaries 7 and 8. □

Remark 4. As long as the set E can be defined Theorem 5 remains true if the condition $p_j \neq p_k$ for all $j \neq k$ is omitted. However, if $p_1 = \ldots = p_m = \bar{p}$, then all lines containing $\bar{p}$ have zero distance to the point set and are optimal. Note that only finitely many normal vectors occur in E for a generic point set, whereas optimal lines with any normal vector exist in the special case $p_1 = \ldots = p_m = \bar{p}$.

3.2.4 Examples

Three points: Three pairwise distinct points p_1, p_2, p_3 form a triangle D. Let A be the area of D. If $j > k$ and $l \neq j, k$, then $f(g_{jk}) = d(p_l, g_{jk})$. Since $2A = \|p_j - p_k\| f(g_{jk})$ for all $j \neq k$, the line g_{jk} is an optimal line if and only if g_{jk} contains the longest edge of the triangle D. If there are two longest edges ($\mathbb{Z}_2$-symmetry) or if D is an equilateral triangle ($\mathfrak{S}_3$-symmetry), then there exist two respectively three geometric L^1-optimal lines.

Four points without symmetry admitting two optimal lines: Let us consider the four points $p_1 = (0,0)^T$, $p_2 = (2,0)^T$, $p_3 = (3,0)^T$, $p_4 = (2,3)^T$ (see Figure 10). If the lines g_{43} or g_{41} were optimal, then there would exist an optimal line containing exactly one of the points p_j. This would contradict Lemma 8, since translation into the direction of p_2 does not change the value of f.

The normal vectors of the lines $g_{21} = g_{31} = g_{32}$ and g_{42} are $n_{21} = (0,1)^T$ respectively $n_{42} = (1,0)^T$. Now $f(0, n_{21}) = 3 = f(2, n_{42})$. Since $n_{21} \neq \pm n_{42}$ there exist exactly two lines with minimal geometric L^1-distance to the set $\{p_1, \ldots, p_4\}$.

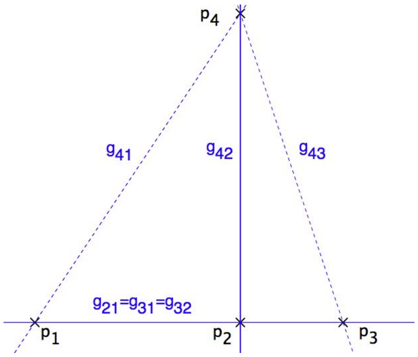

Figure 10:

Invariance under reflection for $m = 5$: Consider the points $p_1 = (-2,1)^T$, $p_2 = (-1,-1)^T$, $p_3 = (0,0)^T$, $p_4 = (1,-1)^T$ and $p_5 = (2,1)^T$ as in subsection 3.1.5 and Figure 6. The lines g_{21}, g_{42}, g_{54} and g_{51} do not fulfill the condition $|J_0| \geq ||J_+| - |J_-||$, since for those lines $|J_0| = 2 < 3 = ||J_+| - |J_-||$.

Now $n_{53} = (1,-2)^T/\sqrt{5}$, $n_{43} = (1,1)^T/\sqrt{2}$, $n_{52} = (2,-3)^T/\sqrt{13}$, $c_{53} = c_{43} = 0$ and $c_{52} = 1/\sqrt{13}$. Using the reflection symmetry we obtain

$$\begin{aligned} f(0, n_{31}) = f(0, n_{53}) &= (4+1+3)/\sqrt{5} = 8/\sqrt{5}, \\ f(0, n_{32}) = f(0, n_{43}) &= (1+2+3)/\sqrt{2} = 6/\sqrt{2} > 8\sqrt{5}, \\ f(c_{41}, n_{41}) = f(c_{52}, n_{52}) &= (8+1+4)\sqrt{13} = \sqrt{13} > 8\sqrt{5}. \end{aligned}$$

The lines g_{31} and g_{53} are not parallel. Hence, $E = \bar{E}$. There are exactly two lines with minimal geometric L^1-distance to the set $\{p_1, \ldots, p_5\}$. These are g_{31} and g_{53}.

4 Maximal distance - L^∞-norm

In this section we minimize the largest of the distances of the single points p_j. We consider the continuous function $f(g) = \max\{d_j : j = 1, \ldots, m\}$. The function f is differentiable if there is exactly one largest d_j. We show the existence of the global minimum of f for the algebraic and the geometric distance. The set of optimal lines is finite in both cases, because optimal lines are located in a special manner between the edges and vertices of the convex polytope generated by $p_1, \ldots, p_m$. Using the vertical distance the function f becomes convex and the global minimum is then attained at a unique line.

4.1 Minimal algebraic L^∞-distance

Given points $p_j = (x_j, y_j)^T \in \mathbb{R}^2$, $j = 1, \ldots, m$, we determine the linear function $y(x) = ax + b$, $a, b \in \mathbb{R}$, with minimal algebraic L^∞-distance to the set $\{p_1, \ldots, p_m\}$, i.e., the minimum of the continuous, piecewise linear and convex function $f : \mathbb{R}^2 \to \mathbb{R}$ defined by $f(a, b) = \max\{|y_j - (ax_j + b)| : j = 1, \ldots, m\}$.

As in the sections 2.1 and 3.1 we additionally assume that $x_j \neq x_k$ for all $j \neq k$ and decompose the index set $\{p_1, \ldots, p_m\}$ into $J_+ = \{j : y_j > y(x_j)\}$, $J_0 = \{j : y_j = y(x_j)\}$ and $J_- = \{j : y_j < y(x_j)\}$. Now

$$f(a, b) = \max\left\{0, \max\{y_j - ax_j - b : j \in J_+\}, \max\{ax_j + b - y_j : j \in J_-\}\right\}.$$

4.1.1 Translation

As in section 3.1.2, we restrict f to lines with arbitrary fixed slope $a \in \mathbb{R}$. Again, set $\beta_j := y_j - ax_j$ and let σ be a permutation satisfying $\beta_{\sigma(1)} \leq \ldots \leq \beta_{\sigma(m)}$ (see Figure 2).

Lemma 9. $\min\{f(a, b) : b \in \mathbb{R}\} = f(a, b_0)$ *if and only if* $b_0 = (\beta_{\sigma(m)} + \beta_{\sigma_{\sigma(1)}})/2$.

Proof. The assertion follows from

$$f(a, b) = \max_{j=1,\ldots,m}\{|\beta_j - b|\} = \max\{|\beta_{\sigma(m)} - b|, |\beta_{\sigma(1)} - b|\} \geq (\beta_{\sigma(m)} - \beta_{\sigma(1)})/2$$

and $\max\{|\beta_{\sigma(m)} - b|, |\beta_{\sigma(1)} - b|\} = (\beta_{\sigma(m)} - \beta_{\sigma(1)})/2 \Leftrightarrow b = (\beta_{\sigma(m)} + \beta_{\sigma_{\sigma(1)}})/2$. ☐

Corollary 10. *If* $\min\{f(a, b) : a, b \in \mathbb{R}\} = f(a_0, b_0)$, *then there exist indices* $k \neq l$ *such that* $f(a_0, b_0) = \beta_l - b_0 = b_0 - \beta_k$ *and the point* $(p_k + p_l)/2$ *lies on the line defined by* $y = a_0 x + b_0$.

Proof. The equation $f(a_0, b_0) = \beta_l - b_0 = b_0 - \beta_k$ holds for $k = \sigma(1)$ and $l = \sigma(m)$. It is easy to check that

$$y\left(\frac{x_k + x_l}{2}\right) = a_0 \frac{x_k + x_l}{2} + b_0 = \frac{1}{2}(a_0 x_k + a_0 x_l + \beta_l + \beta_k) = \frac{y_k + y_l}{2}$$

for the function $y(x) = a_0 x + b_0$. $\square$

4.1.2 Rotation

For any pair of indices (k, l) with $k \neq l$ we consider the values of f at lines containing the point $(p_k + p_l)/2$. The condition $y((x_k + x_l)/2) = (y_k + y_l)/2$ implies $2b = (y_k + y_l) - a(x_k + x_l)$. We investigate the function$f : \mathbb{R} \to \mathbb{R}$ defined by

$$\begin{aligned} f(a) &:= f(a, (y_k + y_l - a(x_k + x_l))/2) \\ &= \max\{|y_j - a x_j - (y_k + y_l)/2 + a(x_k + x_l)/2| : j = 1, \dots, m\} \\ &= \max\{|\tilde{y}_j - a\tilde{x}_j| : j = 1, \dots, m\} \end{aligned}$$

where $\tilde{x}_j := x_j - (x_k + x_l)/2$ and $\tilde{y}_j := y_j - (y_k + y_l)/2$. Note that $\tilde{x}_k, \tilde{x}_l \neq 0$, since the coordinates x_j are pairwise distinct.

Lemma 10. *If* $f(a_0) = \min\{f(a) : a \in \mathbb{R}\}$*,* $f(a_0) = \tilde{y}_l - a_0\tilde{x}_l = a_0\tilde{x}_k - \tilde{y}_k$ *and* $f(a_0) > 0$*, then there exists an index* $j \neq k, l$ *such that* $f(a_0) = |\tilde{y}_j - a_0\tilde{x}_j|$*.*

Proof. Note that $|\tilde{y}_l - a\tilde{x}_l| = |\tilde{y}_k - a\tilde{x}_k|$ holds for all $a \in \mathbb{R}$, because $\tilde{y}_l - a\tilde{x}_l = (x_l - x_k)/2 - a(y_l - y_k)/2$ and $\tilde{y}_k - a\tilde{x}_k = (x_k - x_l)/2 - a(y_k - y_l)/2$. If the inequality $|\tilde{y}_j - a_0\tilde{x}_j| < |\tilde{y}_k - a_0\tilde{x}_k|$ holds for all $j \neq k, l$, then f is differentiable at a_0 and $f'(a_0) = -\tilde{x}_l = \tilde{x}_k \neq 0$. $\square$

4.1.3 Existence and Uniqueness of the optimal line

Corollary 11. *The function* $f : \mathbb{R}^2 \to \mathbb{R}$ *defined by* $(a, b) \mapsto \max\{|y_j - a x_j - b| : j = 1 \dots, m\}$ *admits a global minimum.*

Proof. For any $k \neq l$ the continuous functions investigated in subsection 4.1.2 admit a global minimum, since $\lim_{a \to \pm\infty} |\tilde{y}_j - a\tilde{x}_j| = \infty$ for all j with $\tilde{x}_j \neq 0$. $\square$

If $0 < f(a_0, b_0) = \min\{f(a, b) : a, b \in \mathbb{R}\}$, then Corollary 10 and Lemma 10 imply the existence of three pairwise distinct indices k_1, k_2, k_3 with the following properties: The line $g_{k_1k_2}$ through p_{k_1} and p_{k_2} is parallel to the line given by $y = a_0 x + b_0$, $f(a_0, b_0) = |y_{k_i} - a_0 x_{k_i} - b_0|$ for $i = 1, 2, 3$, and $p_{k_3} \notin g_{k_1k_2}$. Thus, the value $f(a_0, b_0)$ is half of the vertical distance between the point p_{k_3} and the line $g_{k_1k_2}$, i.e.,

$$f(a_0, b_0) = \frac{1}{2}\left| y_{k_3} - y_{k_1} - \frac{y_{k_2} - y_{k_1}}{x_{k_2} - x_{k_1}}(x_{k_3} - x_{k_1}) \right|.$$

Lemma 11. *If* $f(a_0, b_0) = f(a_1, b_1) = \min\{f(a, b) : a, b \in \mathbb{R}\}$, *then* $a_0 = a_1$ *and* $b_0 = b_1$.

Proof. There are only finitely many triples (k_1, k_2, k_3) with the properties described in Lemma 10. Therefore, the global minimum of the function $f(a, b)$ is attained only at finitely many lines. Since f is a convex function, the set of optimal lines is a convex set. Finite convex sets contain at most one element.

This lemma can be proven without making use of the general properties of convex functions directly. We provide this second proof to clarify the link between the uniqueness of the optimal line and the standard assumption $x_j \neq x_k$ for all $j \neq k$: The condition $d = f(a_0, b_0) = f(a_1, b_1)$ implies

$$p_j \in \{(x, y)^T : d \geq |y - a_i x - b_i|, i = 0, 1\} =: M \text{ for all } j.$$

If $a_0 = a_1$, then all points p_j are contained in the intersection of two parallel stripes of vertical width $2d$. This intersection is a parallel stripe of width $< 2d$ if and only if $b_0 \neq b_1$, since

$$M = \{(x, y) : d + \min(b_0, b_1) \geq y - a_0 x \geq -d + \max(b_1, b_0)\}$$

for $a_0 = a_1$.

If $a_1 \neq a_0$, then M is a parallelogram. Using the triangle inequality we obtain $M \subset \{(x, y) : 2d \geq |2y - (a_1 + a_0)x - (b_1 + b_0)|\}$. Since d is the global minimum of the function f, it follows that $f(\frac{a_0+a_1}{2}, \frac{b_0+b_1}{2}) = d$. A small calculation, that again uses the triangle inequality, shows that

$$M \cap \{(x, y) : 2d = |2y - (a_1 + a_0)x - (b_1 + b_0)|\} = \{(x_0, a_0 x_0 + b_0 \pm d)\}$$

for $x_0 = -(b_1 - b_0)/(a_1 - a_0)$. This fact contradicts Corollary 10, since the coordinates x_j are pairwise distinct. □

4.1.4 Summary of the algebraic L^∞-distance

The notions convex hull of the set $\{p_1, \ldots, p_m\}$, edge and vertex are appropriate to effectively characterize the triples of indices with the properties being specified in subsection 4.1.3 .

The convex hull $H(\{p_1, \ldots, p_m\})$ of the points $p_1, \ldots, p_m$ is denoted by P. A point p_k is a vertex of the polytope P, if p_k is not contained in the convex hull of the remaining points p_j, $j \neq k$. The set of vertices is denoted by V, i.e., $V := \{p_k : p_k \notin H(\{p_j : j \neq k\})\}$. The boundary ∂P of the set P consists of line segments of the form $S_{kl} := \{p_l + t(p_k - p_l) : 0 \leq t \leq 1\}$ with $k, l \in V$.

Theorem 6. *Let* $p_j = (x_j, y_j)^T$, $j = 1, \ldots, m$, *such that* $x_j \neq x_k$ *for all* $j \neq k$. *There exists a unique linear function with minimal algebraic* L^∞*-distance to the set* $\{p_1, \ldots, p_m\}$. *Moreover,*

$$\begin{aligned}\min_{a,b\in\mathbb{R}} f(a, b) &= \min_{a,b\in\mathbb{R}} \max_{j=1,\ldots,m} |y_j - a x_j - b| = \min_{a,b\in\mathbb{R}} \max_{p_j\in V} |y_j - a x_j - b| \\ &= \frac{1}{2} \min_{S_{kl}\in\partial P} \max_{p_j\in V} \left| y_j - y_k - \frac{y_k - y_l}{x_k - x_l}(x_j - x_k) \right|.\end{aligned}$$

If $0 < f(a_0, b_0) = \min\{f(a,b) : a, b \in \mathbb{R}\}$*, then there exist pairwise distinct indices* $k_1, k_2, k_3 \in V$ *such that* $f(a_0, b_0) = |y_{k_i} - a_0 x_{k_i} - b_0|$ *for* $i = 1, 2, 3$ *and* $S_{k_1 k_2} \subset \partial P$*.*

Corollary 12. *If the set* $\{p_1, \ldots, p_m\}$ *is invariant under the reflection in the line defined by* $x = \bar{x}$*, then the linear function with minimal algebraic* L^∞*-distance is*

$$y(x) \equiv \frac{1}{2} \left(\max\{y_j : j = 1, \ldots, m\} + \min\{y_j : j = 1, \ldots, m\} \right).$$

Proof. Similar to the proof of Lemma 1 this assertion follows from the uniqueness of the optimal line and Lemma 9. □

Remark 5. Note that the optimal lines with minimal algebraic L^∞-distance depend only on the convex hull P of the points $p_1, \ldots, p_m$. In particular, the minimum of f is equal to zero if and only if P is a line segment, i.e., there are at most two vertices. As long as only edges not parallel to the y-axis are considered, Theorem 6 remains true, if the condition $x_j \neq x_k$ for all $j \neq k$ is weakened to the existence of indices $j \neq k$ satisfying $x_j \neq x_k$.

However, if $x_1 = \ldots = x_m = \bar{x}$, then P is a line segment parallel to the y-axis. The linear functionen $y(x) = a(x - \bar{x}) + b$ has minimal algebraic L^∞-distance to the set $\{p_1, \ldots, p_m\}$ if and only if $a \in \mathbb{R}$ and

$$b = \frac{1}{2} \left(\min\{y_1, \ldots, y_m\} + \max\{y_1, \ldots, y_m\} \right).$$

In contrast to Theorem 6, these are infinitely many optimal lines.

4.1.5 Examples

Three points: As in the first example in subsection 3.1.5 we consider three points $p_j = (x_j, y_j)^T \in \mathbb{R}^2$ with $x_1 < x_2 < x_3$. If p_1, p_2, p_3 are not collinear, then $E = \{p_1, p_2, p_3\}$. Applying the results of subsection 3.1.5 we conclude that the line parallel to S_{31} with equal vertical distance to S_{31} and p_2 has minimal algebraic L^∞-distance to $\{p_1, p_2, p_3\}$, because p_2 is the given point with smallest vertical distance to the corresponding opposite side of the triangle.

Four points: We consider the examples concerning four given points of the subsections 3.1.5 (see Figure 4) and 3.2.4 (see Figure 10). The linear functions with minimal algebraic L^∞-distance can be quickly determined for these given point sets, because three of the four given points are collinear in both cases. Hence, the set of vertices consists of three elements. As in the paragraph above, the optimal line is parallel to the line through the two vertices with smallest respectively largest x-coordinate (see Figures 11 and 12).

Invariance under reflection symmetry: The set of points $p_1, \ldots, p_5$ in Figure 6 ist invariant under reflection in the y-axis. Corollary 12 leads to the optimal linear function $y(x) \equiv 0$, since $\bar{p} = (0, 0)^T$.

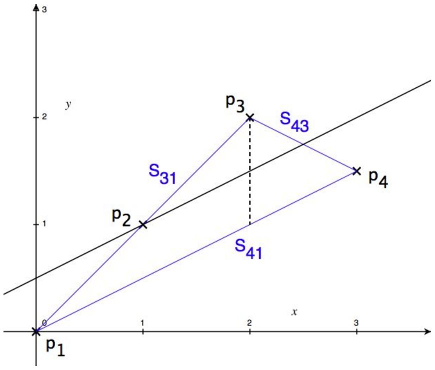

Figure 11:

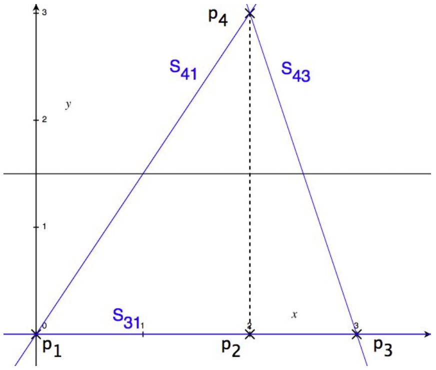

Figure 12:

4.2 Minimal geometric L^∞-distance

Given pairwise distinct points $p_j \in \mathbb{R}^2$, $j = 1, \ldots, m$, we determine lines given by $g = \{q \in \mathbb{R}^2 : c = \langle q, n\rangle\}$, $c \in \mathbb{R}$, $n \in S^1$ with minimal geometric L^∞-distance to the set $\{p_1, \ldots, p_m\}$, i.e., the minimum of the function $f : \mathbb{R} \times S^1 \to \mathbb{R}$ defined by $f(c, n) = \max\{|c - \langle p_j, n\rangle| : j = 1, \ldots, m\}$.

As in subsection 3.2 we decompose the index set $\{1, \ldots, m\}$. For every line $\{q \in \mathbb{R}^2 : \langle q, n\rangle = c\}$ set $J_+ := \{j : \langle p_j, n\rangle > c\}$, $J_0 := \{j : \langle p_j, n\rangle = c\}$ and $J_- := \{j : \langle p_j, n\rangle < c\}$ (see Figure 8). Now

$$f(c, n) = \max\{0, \max\{\langle p_j, n\rangle - c : j \in J_+\}, \max\{c - \langle p_j, n\rangle : j \in J_-\}\}.$$

Similar to the investigation of the algebraic L^∞-distance in section 4.1 we show that the function f admits a global minimum and describe optimal lines by means of edges and vertices of the convex hull of $p_1, \ldots, p_m$. Transferring the statements of section 4.1, note that $f(c, n)$ is convex only in the variable c.

4.2.1 Translation

Set $\gamma_j := \langle p_j, n\rangle$. Let σ be a permutation satisfying $\gamma_{\sigma(1)} \leq \ldots \leq \gamma_{\sigma(m)}$ as in subsection 3.2.1 (see Figure 8).

Lemma 12. *It holds* $\min\{f(c, n) : c \in \mathbb{R}\} = f(c_0, n)$ *if and only if* $c_0 = (\gamma_{\sigma(m)} + \gamma_{\sigma_{\sigma(1)}})/2$.

Proof. Replace b by c, β by γ and a by n in the proof of Lemma 9. ☐

Corollary 13. *If* $\min\{f(c, n) : c \in \mathbb{R}, n \in S^1\} = f(c_0, n_0)$, *then there exist indices* $k \neq l$ *satisfying* $f(c_0, n_0) = \gamma_l - c_0 = c_0 - \gamma_k$ *and* $\langle (p_k + p_l)/2, n_0\rangle = c_0$.

Proof. Replace β by γ and b_0 by c_0 in the proof of Lemma 10. ☐

Corollary 14. *The function* $f : \mathbb{R} \times S^1 \to \mathbb{R}$ *defined by the assignment* $(c, n) \mapsto \max\{|c - \langle p_j, n\rangle| : j = 1, \ldots, m\}$ *admits a global minimum.*

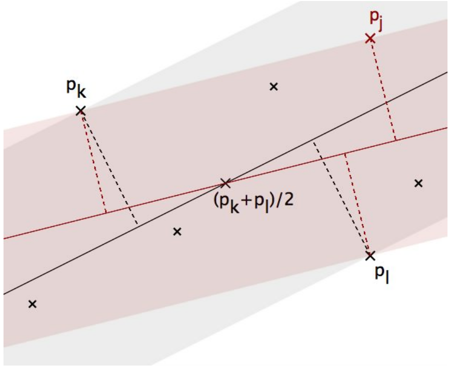

Figure 13:

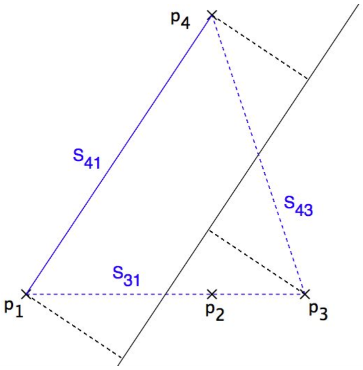

Figure 14:

Proof. There are only finitely many points of the form $(p_k + p_l)/2$ with $k > l$, S^1 is a compact set and the function f is continuous. $\square$

4.2.2 Rotation

For any pair of indices (k, l) with $k \neq l$ we consider the values of f at lines containing the point $(p_k + p_l)/2$. The condition $(p_k + p_l)/2 \in g = \{q : \langle q, n\rangle = c\}$ implies $\langle (p_k + p_l)/2, n\rangle = c$. Therefore, we investigate the function $f : S^1 \to \mathbb{R}$ defined by

$$\begin{aligned} f(n) &:= f(\langle (p_k + p_l)/2, n\rangle, n) \\ &= \max\{|\langle (p_k + p_l)/2, n\rangle - \langle p_j, n\rangle| : j = 1, \ldots, m\} \\ &= \max\{|\langle p_j - (p_k + p_l)/2, n\rangle| : j = 1, \ldots, m\} \\ &= \max\{|\langle \tilde{p}_j, n\rangle| : j = 1, \ldots, m\} \text{ where } \tilde{p}_j := p_j - (p_k + p_l)/2. \end{aligned}$$

Note that $\tilde{p}_k = -\tilde{p}_l \neq 0$, since $\tilde{p}_k = (p_k - p_l)/2$, $\tilde{p}_l = (p_l - p_k)/2$ and $p_k \neq p_l$.

Lemma 13. *If* $f(n_0) = \min\{f(n) : n \in S^1\}$, $f(n_0) = \langle \tilde{p}_l, n_0\rangle = -\langle \tilde{p}_k, n_0\rangle$ *and* $f(n_0) > 0$, *then there exists an index* $j \neq k, l$ *such that* $f(n_0) = |\langle \tilde{p}_j, n_0\rangle|$.

Proof. Note that $\langle \tilde{p}_l, n\rangle = -\langle \tilde{p}_k, n\rangle$ for all $n \in S^1$, since $\tilde{p}_k = -\tilde{p}_l$. If the inequality $|\langle \tilde{p}_j, n(t_0)\rangle| < f(n(t_0))$ holds for all $j \neq k, l$, then the function $h(t) := f(n(t))$ given by the parametrization $n(t) = (\cos t, \sin t)^T$ is differentiable at t_0. Note that $l \in J_+$. Now, $h'(t_0) = \tilde{p}_l^T J n(t_0) = 0$ if and only if there exists $\lambda > 0$ such that $\tilde{p}_l = \lambda n$. If $h'(t_0) = 0$, then $h''(t_0) = \tilde{p}_l^T J J n(t_0) = -\lambda < 0$, since $n \in S^1$ and $J^2 = -\operatorname{Id}$. Consequently, if $|\langle \tilde{p}_j, n(t)\rangle| < h(t)$ for all $j \neq k, l$, then $h(t)$ is not a local minimum. (see Figure 13) $\square$

4.2.3 Summary of the geometric L^∞-distance

Using the notation of subsection 4.1.4 for the convex hull and its edges and vertices we characterize lines with minimal geometric L^∞-distance.

Theorem 7. *Let $p_j \in \mathbb{R}^2$, $j = 1, \ldots, m$, be pairwise distinct points. There exists a line with minimal geometric L^∞-distance to the set $\{p_1, \ldots, p_m\}$. If $0 < f(c_0, n_0) = \min\{f(c, n) : c \in \mathbb{R}, n \in S^1\}$, then there exists pairwise distinct indices $k_1, k_2, k_3 \in V$ such that $f(c_0, n_0) = |\langle p_{k_i}, n_0\rangle - c_0|$ for $i = 1, 2, 3$ and $S_{k_1k_2} \subset \partial P$. Moreover,*

$$\begin{aligned}\min_{c\in\mathbb{R}, n\in S^1} f(c,n) &= \min_{c\in\mathbb{R}, n\in S^1} \max_{j=1,\ldots,m} |\langle p_j, n\rangle - c| = \min_{c\in\mathbb{R}} \max_{p_j\in V} |\langle p_j, n\rangle - c| \\ &= \frac{1}{2} \min_{S_{kl}\in\partial P} \max_{p_j\in V} \frac{|\langle p_j - p_k, J(p_l - p_k)\rangle|}{\|p_l - p_k\|}.\end{aligned}$$

In particular, the set of optimal lines is finite.

Proof. If $p_1, \ldots, p_m$ are not collinear, then Lemma 13 and Corollary 13 imply the following properties of a line g with minimal geometric L^∞-distance to the set $\{p_1, \ldots, p_m\}$: The line g is parallel to an edge $S_{k_1k_2}$ of the polytope P. The geometric distance between any vertex in V and g is less or equal to the geometric distance between $S_{k_1k_2}$ and g. There exists a vertex $p_{k_3} \in E$ such that $p_{k_3} \notin S_{k_1k_2}$ and the geometric distance between g and p_{k_3} is equal to that between g and $S_{k_1k_2}$. Thus, the minimum of f is half of the geometric distance between $S_{k_1k_2}$ and p_{k_3}.

Since $n = J(p_l - p_k)\|p_l - p_k\|^{-1}$ is a normal vector of the line through the points $p_k \neq p_l$, the geometric distance between p_j and S_{kl} is given by $|\langle p_j - p_k, J(p_l - p_k)\rangle|\|p_l - p_k\|^{-1}$. ☐

Remark 6. The geometric, just as the algebraic, L^∞-distance to a point set $\{p_1, \ldots, p_m\}$ depends only on the convex hull of the points $p_1, \ldots, p_m$. Hence, Theorem 7 remains true if the condition $p_j \neq p_k$ for all $j \neq k$ is weakened to the existence two indices $j \neq k$ such that $p_j \neq p_k$. If $p_1 = \ldots = p_m = \bar{p}$, then $P = V = \{\bar{p}\}$ and any line through $\bar{p}$ has minimal distance zero.

4.2.4 Examples

Three points: We consider three pairwise distinct points $p_1, p_2, p_3 \in \mathbb{R}^2$ as in the first example of subsection 3.2.4. If p_1, p_2, p_3 are not collinear, then $V = \{p_1, p_2, p_3\}$. A line g has minimal geometric L^∞-distance to $\{p_1, p_2, p_3\}$ if and only if g is parallel to the longest side s of the triangle and the geometric distance between s and g is equal to the geometric distance between g and the point opposite to s.

Four points: Let us consider the four points $p_1 = (0, 0)^T$, $p_2 = (2, 0)^T$, $p_3 = (3, 0)^T$ and $p_4 = (2, 3)^T$ (see Figure 14). Obviously, $V = \{p_1, p_3, p_4\}$. The edge S_{41} is the unique longest side of the triangle $p_1p_3p_4$. There exists a unique line with minimal geometric L^∞-distance to $\{p_1, \ldots, p_4\}$. This optimal line is parallel to S_{41} and has the same geometric distance to S_{41} and to p_3. Compare this line to the lines with minimal algebraic L^∞-distance (Figure 12) and with minimal geometric L^1-distance (Figure 10), they are all different.

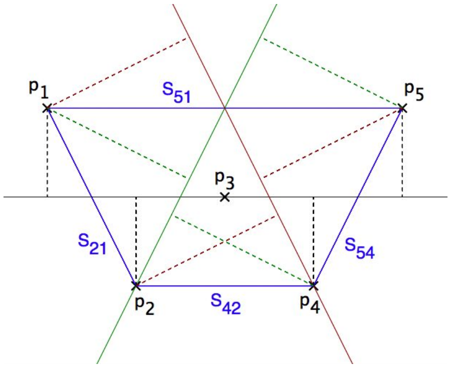

Figure 15:

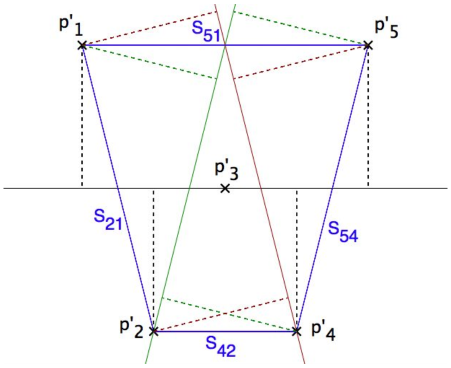

Figure 16:

Invariance under reflection symmetry: Let us consider the five points $p_1 = (-2, 1)^T$, $p_2 = (-1, -1)^T$, $p_3 = (0, 0)^T$, $p_4 = (1, -1)^T$ and $p_5 = (2, 1)^T$ as in the subsections 3.1.5, 3.2.4 and 4.1.5 and Figure 6. The convex hull of the five points is a trapezium with $V = \{p_1, p_2, p_4, p_5\}$ (see Figure 15). We denote the geometric distance between the vertex p_j and the edge S_{kl} by $d(S_{kl}, p_j)$. The edges S_{51} and S_{42} are parallel. It is easy to see that $d(S_{42}, p_5) = d(S_{42}, p_1) = d(S_{51}, p_2) = d(S_{51}, p_4) = 2$. The set $\{p_1, \dots, p_5\}$ is invariant under reflection in the y-axis. Hence, $d(S_{21}, p_5) = d(S_{54}, p_1) = 2d(S_{21}, p_4) = 2d(S_{54}, p_2)$. Using the formula given in Theorem 7 we calculate

$$d(S_{21}, p_5) = \frac{|\langle p_5 - p_2, J(p_1 - p_2)\rangle|}{\|p_1 - p_2\|} = \frac{|(3, 2)J(-1, 2)^T|}{\sqrt{5}} = \frac{8}{\sqrt{5}} > 2.$$

Thus, the unique line with minimal geometric L^∞-distance to the point set $\{p_1, \dots, p_5\}$ is given by the equation $y = 0$.

In this example the line with minimal geometric L^∞-distance is unique and coincides with the line with minimal algebraic L^∞-distance. In contrast to Corollary 12, the invariance under reflection in the line $x = \bar{x}$ does not imply the existence of an optimal line of the form $y = \bar{y}$ for the geometric L^∞-distance, since the optimal line is not unique. Scaling the y-coordinate makes this different behavior more obvious.

We consider the linear map A given by $(x, y) \mapsto (x, \lambda y)$ with $0 < \lambda \in \mathbb{R}$ and $p'_j := A(p_j)$. Now $p'_1 = (-2, \lambda)^T$, $p'_2 = (-1, -\lambda)^T$, $p'_3 = (0, 0)^T$, $p'_4 = (1, -\lambda)^T$ and $p'_5 = (2, \lambda)^T$. The set $\{p'_1, \dots, p'_5\}$ is invariant under reflection in the y-axis for all $\lambda \in \mathbb{R}$. Hence, the linear function $y(x) \equiv 0$ has minimal algebraic L^∞-distance to the set $\{p'_1, \dots, p'_5\}$, since $\bar{p}' = (0, 0)$ for all $\lambda \in \mathbb{R}$. Similar to the calculations above we obtain $V = \{p'_1, p'_2, p'_4, p'_5\}$, $d(S_{42}, p'_1) = d(S_{42}, p'_5) = d(S_{51}, p'_2) = d(S_{51}, p'_4) = 2\lambda$, $d(S_{21}, p'_5) = d(S_{54}, p'_1) = 2d(S_{21}, p'_4) = 2d(S_{54}, p'_2)$ and

$$d(S_{21}, p'_5) = \frac{|\langle p'_5 - p'_2, J(p'_1 - p'_2)\rangle|}{\|p'_1 - p'_2\|} = \frac{|(3, 2\lambda)J(-1, 2\lambda)^T|}{\sqrt{1 + 4\lambda^2}} = \frac{8\lambda}{\sqrt{1 + 4\lambda^2}}.$$

Figure 16 shows the situation for the case $\lambda = 2$. For

$$d(S_{42}, p_1') < d(S_{21}, p_5') \Leftrightarrow \sqrt{1 + 4\lambda^2} < 4 \Leftrightarrow |\lambda| < \frac{\sqrt{15}}{2},$$

the set of lines with minimal geometric L^∞-distance to the set $\{p_1', \dots, p_5'\}$ depends on $\lambda > 0$ as follows: For $\lambda > \sqrt{15}/2$ there are exactly two optimal lines, these are $y = \lambda \pm 2\lambda x$. For $0 < \lambda < \sqrt{15}/2$ the line $y = 0$ is the unique optimal line. For $\lambda = \sqrt{15}/2$ there are exactly three optimal lines, these are $y = 0$ and $y = \lambda \pm 2\lambda x$.

5 L^p-Norm

In this section we want to minimize the L^p-norm of the vector $(d_1, \dots, d_m)$. We consider the function $f(g) = \sum_{j=1}^m d_j^p$ for $p > 1$. This function is continuously differentiable, since the function $\mathbb{R} \to \mathbb{R}$ defined by $x \mapsto |x|^p$ has this property for $p > 1$. The case $p = 2$ has been discussed in section 2.

We show that the function f admits a global minimum for every $p > 1$. For $p \neq 2$ the critical points of f are the solutions of a system of nonlinear equations, which, in general, can not be explicitly resolved by a closed formula.

The function $f(g)$ is convex in some of the parameters of the line g. We apply the following lemmas to prove the existence of a global minimum and properties of the set of optimal lines in the succeeding subsections. Except for a few special examples, e.g., $m = 3$ or symmetries of the point set, it is impossible to provide explicit formulas of L^p-optimal lines. Therefore, the global minimum of f can be determined in most of the situations only numerically.

Lemma 14. *Let* $\xi_j \in \mathbb{R}^n$, $\eta_j \in \mathbb{R}$ *and* $p \geq 1$.
If $\cap_{j=1}^m \xi_j^\perp = \cap_{j=1}^m \{x \in \mathbb{R}^n : \xi_j^T x = 0\} = \{0\}$, *then the function* $f : \mathbb{R}^n \to \mathbb{R}$ *defined by* $f(x) = \sum_{j=1}^m |\xi_j^T x + \eta_j|^p$ *admits a global minimum.*

Proof. The function f is continuous. Set $\tilde{x} := (x, 1)$ and $\tilde{\xi}_j := (\xi_j, \eta_j)$. Now $f(x) = \sum_{j=1}^m |\tilde{\xi}_j^T \tilde{x}|^p$ and

$$f(x) = \|\tilde{x}\|^p \sum_{j=1}^m \left| \tilde{\xi}_j^T \frac{\tilde{x}}{\|\tilde{x}\|} \right|^p \quad \text{for } \tilde{x} \neq 0.$$

The function $\tilde{x} \mapsto \sum_{j=1}^m |\tilde{\xi}_j^T \tilde{x}|^p$ is continuous and admits a global minimum $m \geq 0$ on the compact set $\{\|\tilde{x}\| = 1\} \subset \mathbb{R}^{n+1}$.

If $m = 0$, then there exist $\tilde{x}_0 = (x_0, \lambda)$ with $x_0 \in \mathbb{R}^n$ and $\lambda \in \mathbb{R}$ such that $0 = \tilde{\xi}_j^T \tilde{x}_0 = \xi_j^T x_0 + \eta_j \lambda$ for all j and $\|x_0^2\|^2 + \lambda^2 = 1$. The assumption $\lambda = 0$ would imply $x_0 \neq 0$ and $\xi_j^T x_0 = 0$ for all j contradicting $\cap_{j=1}^m \xi_j^\perp = \{0\}$. Hence, $\lambda \neq 0$ and $0 = f(x_0/\lambda)$ is the global minimum of the function f.

If $m > 0$, then $f(x) \geq (\|x\|^2 + 1)^{p/2} m \geq f(0) \geq 0$ for all x satisfying $\|x\|^2 \geq (f(0)/m)^{2/p} - 1 =: R$. Continuity of f and compactness of the set $\{\|x\|^2 \leq R\} \subset \mathbb{R}^n$ yield the existence of a global minimum. $\square$

Lemma 15. *Let* $f : \mathbb{R}^n \to \mathbb{R}$ *be defined by* $f(x) = \sum_{j=1}^m |\xi_j^T x + \eta_j|^p$ *with* $\eta_j \in \mathbb{R}$, $p > 1$ *and* $\xi_j \in \mathbb{R}^n$ *satisfying* $\cap_{j=1}^m \xi_j^\perp = \cap_{j=1}^m \{v \in \mathbb{R}^n : \xi_j^T v = 0\} = \{0\}$. *If* $x_0, x_1 \in \mathbb{R}^n$ *such that* $f(x_0) = f(x_1) = \min\{f(x) : x \in \mathbb{R}^n\}$, *then* $x_0 = x_1$.

Proof. For f is convex, $f(x_t) = f(x_0) = f(x_1)$ for all $x_t = tx_1 + (1-t)x_0$ with $0 \le t \le 1$. We define $I := \{j : \xi_j^T x_0 + \eta_j = \xi_j^T x_1 + \eta_j = 0\} \subset \{1, \dots, m\}$ and $K := \cap_{j \in I}\{x : \xi_j^T x + \eta_j = 0\} \subset \mathbb{R}^n$. For K is the set of solutions of a system of linear equations, K is an affine subspace of $\mathbb{R}^n$. Thus, K is a convex set. In particular, $x_t \in K$ for all $0 \le t \le 1$.

The restriction of f to K is given by $f|_K(x) = \sum_{j \notin I} |\xi_j^T x + \eta_j|^p$. The functions f and $f|_K$ are twice continuously differentiable for $p \ge 2$. But for $p < 2$ the restriction $f|_K$ is twice continuously differentiable only on the set open subset $U := \cap_{j \notin I}\{x \in K : \xi_j^T x + \eta_j \neq 0\} \subset K$.

If $x_{t_0} \neq x_{t_1}$ and $\xi_{j_0}^T x_{t_0} = \xi_{j_1}^T x_{t_1} = 0$ for $j_0, j_1 \notin I$, then $j_0 \neq j_1$. Since there are only finitely many indices, the intersection $U \cap \{x_t : 1 \le t \le 1\}$ is an open nonempty subset of $\{x_t : 1 \le t \le 1\}$.

Given $x \in K$ and $v \in \mathbb{R}^n$, the sum $x + v$ is an element of K if and only if $\xi_j^T v = 0$ for all $j \in I$. The set $V := \cap_{j \in I}\{w \in \mathbb{R}^n : \xi_j^T w = 0\}$ is a vector space. For any $x \in U$ and $0 \neq v \in V$ we consider the function $h(t) := f(x + tv)$. It holds

$$h''(0) = p(p-1) \sum_{j \notin I} |\xi_j^T x + \eta_j|^{p-2} (\xi_j^T v)^2 > 0.$$

This means that $U \cap \{x_t : 1 \le t \le 1\} \neq \emptyset$ contains exactly one point. Thus, $x_0 = x_1$. $\square$

5.1 Minimal algebraic L^p-distance

Given points $p_j = (x_j, y_j)^T \in \mathbb{R}^2$, $j = 1, \dots, m$, we want to determine the linear function $y(x) = ax + b$, $a, b \in \mathbb{R}$, with minimal algebraic L^p-distance to the set $\{p_1, \dots, p_m\}$, i.e., the minimum of the function

$$f : \mathbb{R}^2 \to \mathbb{R}, \quad f(a, b) = \sum_{j=1}^m |y_j - (ax_j + b)|^p.$$

As for the investigation of the algebraic L^1-, L^2- and L^∞-distance we additionally assume that $x_1, \dots, x_m$ are pairwise distinct.

The function f is continuous, continuously differentiable and convex. Defining the decomposition $J_+ := \{j : y_j > y(x_j)\}$, $J_0 := \{j : y_j = y(x_j)\}$ and $J_- := \{j : y_j < y(x_j)\}$ for every linear function $y(x) = ax + b$ we obtain the partial derivations

$$\begin{aligned} f_b(a, b) &= \sum_{j \in J_-} p|y_j - ax_j - b|^{p-1} - \sum_{j \in J_+} p|y_j - ax_j - b|^{p-1} \\ f_a(a, b) &= \sum_{j \in J_-} px_j|y_j - ax_j - b|^{p-1} - \sum_{j \in J_+} px_j|y_j - ax_j - b|^{p-1}. \end{aligned}$$

Thus, $f(a,b)$ is a global minimum if and only if

$$\sum_{j\in J_-} |y_j - ax_j - b|^{p-1} = \sum_{j\in J_+} |y_j - ax_j - b|^{p-1} \tag{12}$$

and

$$\sum_{j\in J_-} x_j|y_j - ax_j - b|^{p-1} = \sum_{j\in J_+} x_j|y_j - ax_j - b|^{p-1}. \tag{13}$$

If $p = 2n$ with $n \in \mathbb{N}$ and $n \geq 1$, then $f(a,b) = \sum_{j=1}^m (y_j - ax_j - b)^{2n}$, $f_a(a,b) = p\sum_{j=1}^m x_j(y_j - ax_j - b)^{2n-1}$ and $f_b(a,b) = p\sum_{j=1}^m (y_j - ax_j - b)^{2n-1}$. In this case the equations (12) and (13) are polynomials in the variables a and b of degree $p-1$. Even if it possible to eliminate one of the variables, there is no general closed formula that expresses the common solutions of the equations (12) and (13) for $n > 1$ in terms of the coordinates x_j, y_j.

Theorem 8. *Let $p_j = (x_j, y_j)^T$, $j = 1, \dots, m$ such that $x_j \neq x_k$ for all $j \neq k$.*

For any $p > 1$ there exists a unique linear function with minimal algebraic L^p-distance to the set $\{p_1, \dots, p_m\}$. A linear funktion $y(x) = ax+b$ with $a, b \in \mathbb{R}$ has minimal algebraic L^p-distance to the set $\{p_1, \dots, p_m\}$ if and only if a and b satisfy the equations (12) and (13).

Proof. The assertion follows from Lemma 14 and Lemma 15 with $\eta_j = y_j$ and $\xi_j = (-x_j, -1)^T$. The condition $\cap_{j=1}^m \{(a,b)^T \in \mathbb{R}^2 : \xi_j^T (a,b)^T = 0\} = \{0\}$ is satisfied, since $j > 1$ and $x_j \neq x_k$ for all $k \neq j$. □

Corollary 15. *If the set $\{p_1, \dots, p_m\}$ is invariant under the reflection in the line given by $x = \bar{x}$, then the unique line with minimal algebraic L^∞-distance to $\{p_1, \dots, p_m\}$ is the graph of the linear function*

$$y(x) \equiv b_0 \text{ where } \sum_{y_j > b_0} (y_j - b_0)^{p-1} = \sum_{y_j < b_0} (b_0 - y_j)^{p-1}.$$

Proof. Since there is a unique optimal linear function, the proof is similar to that of Corollary 1. The condition on b_0 follows from equation (12). □

Remark 7. Theorem 8 remains true if the condition $x_j \neq x_k$ for all $j \neq k$ is weakened to the existence of indices $j \neq k$ such that $x_j \neq x_k$, since even in that cases $\cap_{j=1}^m \{(a,b)^T \in \mathbb{R}^2 : \xi_j^T (a,b)^T = 0\} = \{0\}$.

However, if $x_1 = \ldots = x_m = \bar{x}$, then the values of $f(a, b - a\bar{x})$ are independent from a and there exists a unique $b_0 \in \mathbb{R}$ such that $f(0, b_0) \leq f(0, b)$ for all $b \in \mathbb{R}$. Thus, there are infinitely many linear functions with minimal algebraic L^p-distance to $\{p_1, \dots, p_m\}$. These are exactly $y(x) = a(x - \bar{x}) + b_0$ with $a \in \mathbb{R}$.

5.2 Minimal geometric L^p-distance

Given pairwise distinct points $p_j \in \mathbb{R}^2$, $j = 1, \dots, m$, we want to determine the lines given by $g = \{q \in \mathbb{R}^2 : \langle q, n \rangle = c\}$, $c \in \mathbb{R}$, $n \in S^1$, with minimal geometric

L^p-distance to the set $\{p_1, \ldots, p_m\}$, i.e., the minimum of the function

$$f : \mathbb{R} \times S^1 \to \mathbb{R}, \quad f(c,n) = \sum_{j=1}^{m} |c - \langle p_j, n\rangle|^p.$$

As for the investigation of the geometric L^1-, L^2- and L^∞-distance we decompose the index set, this means $J_+ := \{j : \langle p_j, n\rangle > c\}$, $J_0 := \{j : \langle p_j, n\rangle = c\}$, $J_- := \{j : \langle p_j, n\rangle < c\}$ (see Figure 8). Using the parametrization $n(t) = (\cos t, \sin t)^T$ we obtain the following partial derivations of the function $f(c, n(t))$:

$$f_c(c,n) = p \sum_{j \in J_-} |c - \langle p_j, n\rangle|^{p-1} - p \sum_{j \in J_+} |c - \langle p_j, n\rangle|^{p-1}$$

$$f_t(c,n) = p \sum_{j \in J_+} |c - \langle p_j, n\rangle|^{p-1} p_j^T Jn - p \sum_{j \in J_-} |c - \langle p_j, n\rangle|^{p-1} p_j^T Jn$$

If $f(g)$ is a local minimum and the line g is given by $\langle q, n\rangle = c$ with $c \in \mathbb{R}$ and $n \in S^1$, then

$$\sum_{j \in J_-} |c - \langle p_j, n\rangle|^{p-1} = \sum_{j \in J_+} |c - \langle p_j, n\rangle|^{p-1} \tag{14}$$

and

$$\sum_{j \in J_-} |c - \langle p_j, n\rangle|^{p-1} p_j^T Jn = \sum_{j \in J_+} |c - \langle p_j, n\rangle|^{p-1} p_j^T Jn. \tag{15}$$

The equations (14) and (15) are polynomials in c and n respectively real analytic expressions in c and t if $p = 2n$ with $n \in \mathbb{N}$. Except for $p = 2$, there is no general explicit formula of the solutions of the equation $df = (0, 0)$.

Theorem 9. *Let $p_j \in \mathbb{R}^2$, $j = 1, \ldots, m$ be pairwise distinct points.*

For any $p > 1$ there exists a line with minimal geometric L^p-distance to the set $\{p_1, \ldots, p_m\}$. If the line $g = \{q \in \mathbb{R}^2 : \langle q, n\rangle = c\}$ with $c \in \mathbb{R}$ and $n \in S^1$ has minimal geometric L^p-distance to the set $\{p_1, \ldots, p_m\}$, then c and n satisfy the equations (14) and (15).

If $f(c_0, n') = f(c_1, n') = \min\{f(c,n) : c \in \mathbb{R}, n \in S^1\}$, then $c_0 = c_1$.

Proof. Applying Lemma 14 and Lemma 15 with $\eta_j = -\langle p_j, n\rangle$ and $\xi_j = (1)$ it follows that for any $n \in S^1$ there exists a unique $c_n \in \mathbb{R}$ such that $f(c_n, n) = \min\{f(c,n) : c \in \mathbb{R}\}$. Since the function $c \mapsto f(c,n)$ is continuously differentiable, equation (14) yields $\sum_{j \in J_-} |c_n - \langle p_j, n\rangle|^{p-1} = \sum_{j \in J_+} |c_n - \langle p_j, n\rangle|^{p-1}$. In particular, $J_+, J_- \neq \{1, \ldots, m\}$ for any line $g = \{q : c_n = \langle q, n\rangle\}$. Thus,

$$a := \min_{j=1,\ldots,m,\, n \in S^1} \langle p_j, n\rangle \leq c_n \leq \max_{j=1,\ldots,m,\, n \in S^1} \langle p_j, n\rangle =: b$$

for all $n \in S^1$. The continuous function $f : \mathbb{R} \times S^1 \to \mathbb{R}$, $(c,n) \mapsto f(c,n)$, admits a global minimum on the compact set $[a,b] \times S^1$. □

Remark 8. Theorem 9 remains true if the condition $x_j \neq x_k$ for all $j \neq k$ is omitted.

Remark 9. If the set

$$M := \{(c_0, n_0) : f(c_0, n_0) \leq f(c, n) \, \forall c \in \mathbb{R}, n \in S^1\} \subset \mathbb{R} \times S^1$$

is infinite, then M has an accumulation point, because $M \subset [a, b] \times S^1$. If $p = 2n$ with $n \in \mathbb{N}$, then the existence of such a limit point in M implies that for any $n \in S^1$ there exists $c_n \in \mathbb{R}$ such that $(c_n, n) \in M$, since f is a polynomial in c and n. If $p \notin 2\mathbb{N}$, then, in general, the function $f(c, n)$ is not real analytic. We denote the set of normal vectors of optimal lines by N, i.e., $N := \{n \in S^1 : \mathbb{R} \times \{n\} \cap M \neq \emptyset\}$. If $p \in 2\mathbb{N}$, then N is finite or $N = S^1$. Is this fact true for any $p > 1$?

The lines with minimal geometric L^p-distance to the vertices of an equilateral triangle are identified in [7] by taking advantage of the symmetries of the point set for all $1 \leq p \leq \infty$. In this simplest nontrivial situation the set M consists of three optimal lines for $p > 1$ with $p \neq 2, 4/3$ and $N = S^1$ for $p = 4/3$ and $p = 2$.

A Convexity

A subset $K \subset \mathbb{R}^n$ is called convex if the line segment $\{tx_1 + (1-t)x_0 : 0 \leq t \leq 1\}$ is contained in K for any $x_0, x_1 \in K$. The convex hull $H(K)$ of a set $K \subset \mathbb{R}^n$ is given by $H(K) := \{x = tx_1 + (1-t)x_0 : x_0, x_1 \in K, 0 \leq t \leq 1\}$. A subset $K \subset \mathbb{R}^n$ is convex if and only if $K = H(K)$. Convex sets are connected.

Let $K \subset \mathbb{R}^n$ be a convex set. A function $f : K \to \mathbb{R}$ is called convex if the inequality

$$f(tx_1 + (1-t)x_0) \leq tf(x_1) + (1-t)f(x_0) \tag{16}$$

holds for all $x_0, x_1 \in K$ and all $0 \leq t \leq 1$. The function f is called strictly convex if the inequality (16) is strict for all $t \in (0, 1)$ and $x_0 \neq x_1$. If $K_1 \subset K_2 \subset \mathbb{R}^n$ are two convex sets and the function $f : K_2 \to \mathbb{R}$ is convex, then the restriction $f|_{K_1} : K_1 \to \mathbb{R}$ is convex.

Lemma 16. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be a convex function. The set*

$$M := \{x \in \mathbb{R}^n : f(x) \leq f(y) \text{ for all } y \in \mathbb{R}^n\}$$

is convex. If f is strictly convex, then M contains at most one element.

Proof. The following inequality holds for all $0 \leq t \leq 1$ and $x_0, x_1 \in \mathbb{R}^n$:

$$f(tx_1 + (1-t)x_0) \leq tf(x_1) + (1-t)f(x_0) \leq \max\{f(x_0), f(x_1)\}$$

If $x_0, x_1 \in M$, then $f(tx_1 + (1-t)x_0) = f(x_0) = f(x_1)$, i.e., $tx_1 + (1-t)x_0 \in M$.

If f is strictly convex, $x_0 \neq x_1 \in \mathbb{R}^n$ and $0 < t < 1$, then

$$f(tx_1 + (1-t)x_0) < tf(x_1) + (1-t)f(x_0) \leq \max\{f(x_0), f(x_1)\}.$$

Consequently, $\{x_0, x_1\} \not\subset M$. □

Lemma 17. *For any $\xi \in \mathbb{R}^n$ the linear function $y : \mathbb{R}^n \to \mathbb{R}$ defined by $y(x) = \xi^T x$ is convex.*

Proof. It holds $y(tx_1 + (1-t)x_0) = \xi^T(tx_1 + (1-t)x_0) = t\xi^T x_1 + (1-t)\xi^T x_0 = ty(x_1) + (1-t)y(x_0)$. ☐

Lemma 18. *If $f, g : \mathbb{R}^n \supset K \to \mathbb{R}$ are convex functions on a convex set K, then $f + g$ and $\max\{f, g\}$ are convex functions on K.*

If f or g are additionally strictly convex, then $f + g$ is strictly convex. If f and g are strictly convex, then $\max\{f, g\}$ is strictly convex.

Proof. Applying the inequality (16) to f and g we obtain

$$\begin{aligned}(f+g)(tx_1 + (1-t)x_0) &= f(tx_1 + (1-t)x_0) + g(tx_1 + (1-t)x_0)\\ &\leq tf(x_1) + (1-t)f(x_0) + tg(x_1) + (1-t)g(x_0)\\ &= t(f+g)(x_1) + (1-t)(f+g)(x_0).\end{aligned}$$

Since $t \geq 0$ and $1 - t \geq 0$, it follows that

$$\begin{aligned}\max\{f,g\}(tx_1 + (1-t)x_0) &= \max\{f(tx_1 + (1-t)x_0), g(tx_1 + (1-t)x_0)\}\\ &\leq \max\{tf(x_1) + (1-t)f(x_0), tg(x_1) + (1-t)g(x_0)\}\\ &\leq t\max\{f(x_1), g(x_1)\} + (1-t)\max\{f(x_0), g(x_0)\}\\ &= t\max\{f,g\}(x_1) + (1-t)\max\{f,g\}(x_0).\end{aligned}$$

☐

Corollary 16. *The function $\mathbb{R} \to \mathbb{R}$ defined by $x \mapsto |x|$ is convex.*

Proof. $|x| = \max\{x, -x\}$ ☐

Lemma 19. *Let $K_f \subset \mathbb{R}$ and $K_g \subset \mathbb{R}^n$ be convex sets and $f : K_f \to \mathbb{R}$ and $g : K_g \to \mathbb{R}$ be convex functions satisfying $g(K_g) \subset K_f$. If f is an increasing function on K_f, then $f \circ g : K_g \to \mathbb{R}$ is a convex function.*

Proof. The inequality $g(tx_1 + (1-t)x_0) \leq tg(x_1) + (1-t)g(x_0)$ holds for all $x_0, x_1 \in K_g$ and for all $0 \leq t \leq 1$. The monotony and the convexity of f imply

$$\begin{aligned}(f \circ g)(tx_1 + (1-t)x_0) &= f(g(tx_1 + (1-t)x_0)) \leq f(tg(x_1) + (1-t)g(x_0))\\ &\leq tf(g(x_1)) + (1-t)f(g(x_0))\\ &= t(f \circ g)(x_1) + (1-t)(f \circ g)(x_0).\end{aligned}$$

☐

Lemma 20. *Let $K \subset \mathbb{R}$ be a convex set. If $f : K \to \mathbb{R}$ is a convex twice continuously differentiable function, then $f''(x) \geq 0$ for all $x \in \mathbb{R}$.*

Proof. For any $a \in K$ we consider the function $h(x) := f(x) - (x-a)f'(a) - f(a)$. Now $h(a) = 0$, $h'(a) = 0$, $h''(a) = f''(a)$. The function f is convex if and only if h is convex. The convexity of h implies

$$h(a) = h\left(\frac{a-\varepsilon}{2} + \frac{a+\varepsilon}{2}\right) \leq \frac{1}{2}(h(a-\varepsilon) + h(a+\varepsilon)) \leq \max((h(a-\varepsilon), h(a+\varepsilon))$$

for all ε. Hence, $h(a)$ is not a strict local maximum and $h''(a) \geq 0$. □

Lemma 21. *Let $K \subset \mathbb{R}$ be a convex set and $f : K \to \mathbb{R}$ be a convex function. If $f''(x) \geq 0$ for all $x \in K$, then f is convex. If $f''(x) > 0$ for all $x \in K$, then f is strictly convex.*

Proof. For any $x_0, x_1 \in K$ and $0 < t < 1$ we set $x_t := tx_1 + (1-t)x_0$ and consider the function $h(x) := f(x) - (x - x_t)f'(x_t) - f(x_t)$. Now $h(x_t) = 0$, $h'(x_t) = 0$ and $h''(x) = f''(x)$.

If $h''(x) \geq 0$ for all $x \in K$, then $h'(x)$ is increasing. There exist $a, b \in K$ such that $a \leq x_t \leq b$, $h'(x) = 0$ for all $a \leq x \leq b$, $h'(x) < 0$ for all $x < a$ and $h'(x) > 0$ for all $x > b$. Hence, $h(x) \geq 0$ for all $x \in K$. Now $th(x_1) + (1-t)h(x_0) \geq 0$ implies

$$\begin{aligned} 0 \leq\ & t(f(x_1) - (x_1 - x_t)f'(x_t) - f(x_t)) \\ & + (1-t)(f(x_0) - (x_0 - x_t)f'(x_t) - f(x_t)) = tf(x_1) + (1-t)f(x_0) - f(x_t) \end{aligned}$$

If $h''(x) > 0$ for all $x \in K$, then the inequality above is strict for $0 < t < 1$. □

Corollary 17. *For any $p > 1$ the function $f : [0, \infty) \to \mathbb{R}$ given by $x \mapsto x^p$ is strictly convex.*

Proof. It holds $f''(x) = p(p-1)x^{p-2} > 0$ for all $x > 0$. If $x_0 = 0$, $x_1 > 0$ and $0 < t < 1$, then

$$f(tx_0 + (1-t)x_1) = f((1-t)x_1) = (1-t)^p x_1^p < (1-t)f(x_1) = tf(x_0) + (1-t)f(x_1),$$

since $0 < 1-t < 1$ and $(1-t)^p < (1-t)$. □

Corollary 18. *Let $K \subset \mathbb{R}^n$ be a convex set. If $f : K \to \mathbb{R}$ is convex and twice continuously differentiable, then $H_f(x) \geq 0$ for all $x \in K$.*

Proof. It holds $v^T H_f(x) v = h''(0) \geq 0$ for all $x \in K$ and for all $v \in \mathbb{R}^n$, since $h(t) := f(x + tv)$ is a convex function. □

Corollary 19. *Let $K \subset \mathbb{R}^n$ be a convex set and $f : K \to \mathbb{R}$ be a differentiable function. If $H_f(x) \geq 0$ for all $x \in K$, then f is convex. If $H_f(x) > 0$ for all $x \in K$, then f is strictly convex.*

Corollary 20. *For any $\xi \in \mathbb{R}^n$ and any $p \geq 1$ the function $\mathbb{R}^n \to \mathbb{R}$ defined by $x \mapsto |\xi^T x|^p$ is convex.*
